An important variation of these conditions supervenes when a centralized political authority is developed. The evolution of such an authority is not universal; in many parts of Africa the normal landholding aggregate is still the kinship group, and the authority controlling the use of land lies within the clan; but where chiefdoms exercising effective authority over wider areas have been established, they have tended to encroach on the rights of heads of kinship groups in the disposal of lands. That process, for instance, went far among the Chaga, and among the Ganda, where clan ownership tended to retain little more than a religious or traditional significance. The power of the chief as the ultimate authority over land was strongly marked in those parts of British and French West Africa which came under Islamic influences,¹ as well as in areas such as Dahomey, Benin, or Ashanti. It has been noted, for instance, that in Dikwa, in the British Cameroons, there are three conceptions of land tenure coexisting, due to successive waves of immigration, the last in order representing the political influence of the ruling emir.² References given in previous pages to Swaziland³ and Basutoland⁴ will illustrate the extent of the authority which the paramount chiefs acquired in dealing with questions relating to the disposal of land. The fact that in numerous cases the growth of political organization placed the final authority over land in other hands than those of kindred or group representatives has had a marked significance in the history of Africa. As has been shown,⁵ it was assumed to be the basis of the authority on which chiefs acted in making treaties or agreements with Europeans, and these agreements, though often intended by the chiefs to concede only political control, were in practice frequently treated by the recipients as ceding actual ownership of tribal lands.

The nature of the power which chiefs may have possessed under African custom to cede tribal lands to non-natives has frequently been debated; it is not a question to which it is

¹ See Chap. IX, p. 417.

² *Report to the League of Nations on the Cameroons, 1924*, appendix iii.

⁵ *Ibid.*, p. 801.

easy to give a precise answer or one of general application. Moslem law, evolved in more complex conditions than those of Bantu Africa, made provision for the sale and transfer of property, and the ruler of a Moslem state had a position which would enable him to claim the right to dispose of lands on behalf of the state. On a strict interpretation of the Moslem law, the emirs of the northern provinces of Nigeria or Lake Chad might be held to have this power, but as has already been observed, the Moslem law relating to property, if ever applying in full force, was progressively modified to meet the local custom of the conquered people. Even in Moslem states, therefore, the right of the chief to dispose of lands occupied by his subjects may be open to some question: in non-Moslem Africa the circumstances in which an alienation of tribal lands could be contemplated had never arisen before the days of European penetration, so that in the absence of actual cases which could constitute a native custom, the attribution to chiefs of the power to sell tribal lands could only be a matter of inference. The agreements under which such lands were ceded to European governments dealt with conditions which in almost every case were outside the experience of the chiefs who made them, and their implications must usually have been beyond the power of their makers to envisage. Save, however, where these agreements have still the value of a treaty, as in the case of Basutoland, Barotseland, or Buganda, the conditions in which they were made, and the interpretations subsequently placed on them, are now mainly of historic interest, since the authority of the chief to transfer lands to non-natives has been brought under a control which now places on the administration the responsibility of interpreting its extent and supervising its use. It still remains of importance, however, in regard to the disposal of land to natives, and reference has been made in a previous part of this chapter to some of the problems arising from its exercise.¹

It is usual to speak of the customary land system of Africa as collective or communal, and it is convenient to retain these terms, subject to an appreciation of the limits within which they apply. Some distinction may legitimately be drawn between the collective idea and its expression in a system of landholding. It is true to

¹ See above, pp. 801-2.

say that throughout that part of Africa with which we are concerned there is a prevailing conception of the land as the collective possession of the tribe or group, reinforced in many cases by religious beliefs which ascribe the fertility of the soil and the general prosperity of the inhabitants to the influence of the ancestral spirits with whom the land is associated. Through such beliefs, and through traditions which base the collective claim to tribal lands on the settlement of their first ancestors under a mythical chief, the land may be said to represent the past as well as the future of the tribe; as has been said of the Ashanti, the 'land laws of to-day appear but the logical outcome of a belief which, in the not very remote past, considered the living landowners as but holding as it were tenancies at will from the dead, and as being the trustees of the latter'.¹ The intense antagonism which has been evinced by the native peoples of the Gold Coast to any proposal to modify the customary system has been ascribed to the strength of this religious feeling; though it may be noted that such feelings have not deterred the chiefs of this region from making concessions on a largescale. Elsewhere it has presented difficulties when equivalent land is offered in compensation to the native occupiers of land required for alienation; in their eyes no other land can be equivalent to that in which their essential religious beliefs are centred. It is, however, necessary to remark that this attitude is not universal: there are tribes whose occupation of their present territory is of relatively recent date, who preserve their link with the ancestors through hearth-stones or other relics carried with them on their migrations. Among nomadic herdsmen it is naturally absent.

Viewed as a type of land tenure, the element of collectivity shows itself mainly in the existence of the privilege of occupying lands hitherto undistributed but within the general control of the community; though the lands occupied by a unit, such as a family, are seldom demarcated (and, indeed, could hardly be demarcated in cases where the shifting system of cultivation prevails), their limits are known and respected, and possession is seldom disturbed so long as the occupation is in any sense effective. The community has no claim on the produce of the soil, other than the well-recognized right to hospitality or of assistance at times of scarcity or the

¹ R. S. Rattray, *Ashanti*, 1923, p. 216.

like. Even though the chief, in areas where centralized political institutions have developed, may have the right to evict a subject for misconduct or disloyalty, this is in effect only one aspect of a recognized political penalty; in many cases, indeed, the penalty might take the form of driving a man out of the community while leaving the land to his heirs. In practice, therefore, a reasonable security of tenure existed, if only because a chief, or his dependent sub-chief, has usually been anxious to retain or increase his following; if there has been insecurity, it has been due to the relations between chief and tribesmen in the matter of tribal obligations, and has not been of the nature of the insecurity of a tenant subject to a landlord under conditions of competitive rental. All the incidents of the system are those attaching to conditions in which the supply of land normally exceeds the demand, and where cultivation is in large measure of the 'extensive' type.

There can in former times have been few cases where the formation of land custom came under the influence of the opposite situation, that, namely, in which there is such density of population as to create pressure on the soil; the only large blocks marked by such density were in the region of Lake Victoria, certain areas in Northern and Southern Nigeria, and the Gold Coast; there were smaller examples of this type in the volcanic lands of Kilimanjaro or among the Gishu on the western slopes of Mount Elgon, and in the coastal areas of British and French West Africa. But even where there was pressure on the soil, land cannot have acquired a negotiable value, so long as husbandry conformed mainly to the conditions of a subsistence economy, and there was no regular system of marketing of crops. There is, it is true, evidence that a tribe or group frequently made arrangements to admit outsiders to their lands; such arrangements have been described in detail among the Chaga, Kamba, Haya, the Yakö, and Kikuyu.¹ Though gifts of some kind were given on admission, these transactions did not amount in any sense to sale of lands; they signalized rather the affiliation of the new-comer to the land-owning group, and as soon as a shortage began to be felt, the feeling that the land was the inalienable property of the group led to a reassertion by its members of their hereditary claims.

¹ For studies on these tribes see below, pp. 838-40.

An instance of the alienation of land by one tribe to another before the advent of the Europeans is that of the grant of two large tracts of land by the Wabena to the Ngoni; the transfer of rights was made for defensive reasons, and did not imply the submission of the Ngoni to the Wabena chief.¹ Again, within the group itself there has been in some areas a recognized custom of 'pledging' of land, which presents some resemblance to a possessory mortgage. The evidence of this custom is, as would be expected, strongest in areas where density is greatest. By this custom the creditor has the use of the land until the debt is paid; but here again the central conception which lies behind the affiliation process still prevails; the pledger and his kindred do not lose the equity of redemption. It is an accepted axiom, in the words of the Kikuyu saying, that 'a debt on land can never be finished'.² A pledge of which circumstances have prevented the redemption may constructively amount to sale; the basic principle, however, is that of a redeemable pledge; indeed, the persistence of the right of redemption has in modern conditions frequently been pleaded as a defence against the recognition of sale when transactions, having all the appearance of complete transfers, have come before the European courts, and it has furnished the chief ground on which native opinion has argued the invalidity of the agreements made by chiefs for the surrender of land to non-natives. The conception would appear to have been strong enough to resist even the influence of Koranic law.³ Even in the cases (which, as will be seen, are not numerous) where the right of transfer seems to have gained some recognition, there are certain types of family land which are for religious reasons held to be inalienable, and in some areas special formalities have been required before a transfer can be recognized.⁴

(b) *Studies of Land Tenure*

Over the larger part of Africa these basic conceptions still regulate the customary tenure of lands, though they may be sub-

¹ A. T. and G. M. Culwick, *Ubena of the Rivers*, 1935, p. 242.

ject to local variations due to economic or political conditions. A close study of these customs by administrations is essential to secure the smooth working of the native land system, and governments have in the past admittedly erred in more than one instance for lack of such special knowledge. The reservation of a large area of land for the Buganda king and his chiefs in 1900¹ was an act of political expediency, but the decision that the rights granted over it should take a form which was practically that of freehold produced untoward consequences, not merely by overlooking the existence of clan rights in the soil, but, even more important, by neglecting to realize its inevitable effect on the traditional relationship of the peasants to the chiefs. In French Equatorial Africa and the Belgian Congo the governments failed to see that a collective system could give an illusory appearance of 'vacancy' to lands over which, in fact, recognizable rights existed.² In commenting on a study made of the Yoruba land systems, the Governor of Nigeria³ admitted that the failure to study existing land tenures had led to mistakes in the past; a similar admission was made in the official report on the North Kavirondo tenures in Kenya.⁴ The mistakes of the past have arisen mainly in connexion with rights over native land of which the administration desired to take possession, or with legislative measures conferring upon native landholders titles implying rights not sanctioned by native custom. There are now other spheres of action in which difficulties may arise through the absence of adequate information. One example is to be found in the measures being taken for the encouragement of more efficient methods of cultivation. Such measures include, in Tanganyika the creation of model holdings of an economic size, in Southern Rhodesia, of the demarcation of some reserves into fixed areas for grazing and cultivation, in French West Africa, native colonization schemes, and in several territories, systems of rotational grazing. All these measures, if introduced without full knowledge of the rights existing over the land to which they are applied, may create such resentment as would seriously prejudice the proposed improvements. Attempts to investigate the land

system of the Ibo led to bloodshed, and are still attended with risk.¹ Special care is needed where land is sought for the settlement of populations transferred from sleeping-sickness areas; to establish within the jurisdiction of a native authority persons belonging to a community whose system of land tenure is different from that locally recognized may lead to political friction.

In the Union the government has initiated no specific inquiry on this subject; the reports of the Natal Native Commission of 1881-2, the Cape Native Laws and Customs Commission 1883-5, and the South African Native Affairs Commission of 1903-5 all contain sections referring to native land custom, but they are not based on special investigations made for the purpose. The anthropological studies made of native life in the Union may be said to have paid more attention to economic conditions than to the details of land tenure;² though there is a careful study of the subject in recent work on the Pondoland native by M. Hunter.³ In the Bechuanaland Protectorate there is a study of land tenure by I. Schapera and G. P. Lestrade.⁴ In Southern Rhodesia no special study is available; in Northern Rhodesia there is much useful information in the reports of the commissions to which reference has been made elsewhere,⁵ but no specific inquiry has been made through government or other agencies. The same is true of Nyasaland. In Tanganyika the land customs of the Chaga have been studied by B. Gutmann⁶ and A. W. M. Griffiths,⁷ who also made a study of the special tenures in Bukoba, and the tenures in Ukerewe Island were described by E. C. Baker;⁸ those of Ubena have been examined by A. T. and G. M. Culwick;⁹ there are notes of the general land custom of the Bantu tribes in Kenya and Tanganyika in a study made by the Hon. C. Dundas.¹⁰ In Kenya, government committees investigated the customs of the Kikuyu¹¹ in 1929, and those in the

North Kavirondo reserve¹ in 1930: the former is of value, but the second inquiry was limited to the collection of information over a period of about two weeks from representative headmen summoned to meet the committee. In the Uganda Protectorate land tenures formed the subject of an inquiry made by Sir W. M. Carter² in 1906-7, largely by the questionnaire method, and a committee also reported in 1931 on *kibanja* tenure in Bunyoro.³ The land customs of the Lango have been dealt with by J. H. Driberg,⁴ and those of the Ganda by L. P. Mair.⁵

In Northern Nigeria land rights, as has already been mentioned, were examined by a committee in 1910,⁶ and government initiated an inquiry on the subject by means of a questionnaire directed to its officers in 1929.⁷ The *Gazetteers* of the northern provinces published in 1920 contain some treatment of land tenures, but these do not appear to represent the result of specific inquiries; C. K. Meek's *The Northern Tribes of Nigeria* (1925) and *Tribal Studies in Northern Nigeria* (1931) also give some information. For Southern Nigeria some aspects of land rights were investigated by the West Africa Lands Committee of 1912, which was, however, primarily concerned with the questions arising in the Gold Coast; no report was ever published, but the minutes of evidence contain much valuable information on systems of tenure.⁸ The general nature of the land tenures was described in 1910 by C. W. Alexander,⁹ certain specific aspects of rights in Ibadan were inquired into by Sir E. A. Speed in 1916,¹⁰ and a study of the land customs in the Yoruba Provinces was made by H. L. Ward Price in 1932,¹¹ which constitutes, perhaps, the most important contribution to our knowledge of land custom in this part of Africa. Northcote Thomas's study of the Ibo,¹² and C. K. Tribe, 1937, which also deals with the Ibo, give a great deal of useful information. A detailed memorandum on Ibo land tenure in the village of Umueke Agbaja was prepared by Miss Green, a Leverhulme Trust Fellow, in 1938.¹ A detailed analysis of land tenure in one small community (the Yakö) has been made by C. Daryll Forde.² For the Gold Coast a report on *Customs Relating to the Tenure of Land* was issued in 1895; some of the general aspects of the subject are examined in the commentary on the census of 1931,³ and reference to the judicial decisions bearing on land custom is to be found in legal works, such as those of J. R. Danquah⁴ and J. M. Sarbah.⁵ In Sierra Leone the main principles of native law were briefly described by J. C. Maxwell in 1912,⁶ and a study of the Temne was published in 1913 by Esu Biyi.⁷

In the French territories the inquiry made by the Commission of 1915⁸ appears to have been directed mainly to questions bearing on the proposals for modifying the law relating to the alienation of land. The general nature of the native custom in regard to land was analysed by M. Delafosse in a memorandum of 1911,⁹ and is further dealt with in his work on native custom;¹⁰ the land customs of the Agni were described by him with M. Villamur in 1906.¹¹ This tribe is also discussed in two articles by F. Clozel, published in 1901 and 1906. Land custom in the Cameroons is referred to in Tessmann's *Die Pangwe*, 1912. The series of studies of local custom now being undertaken in French West Africa, to which reference is made elsewhere,¹² is designed to embrace inquiries on native land tenures and will make a useful contribution to existing knowledge on the subject.¹³ In the Belgian Congo no inquiry has

yet been instituted by government, but certain studies have been issued, such as those of M. Duchesne,¹ relating to rights in connexion with palm groves, and M. Van der Kerken.² There are also descriptions of land custom contained in more general works,³ and in a legal review published in the territory.⁴

The material on the subject of native land custom may with justice be described as of very unequal value. The specific studies undertaken are, as will have been seen, few in number, and the method adopted has not always been well considered. Inquiry by means of a questionnaire directed to officers or selected chiefs and headmen, though perhaps the only method possible at an early stage of occupation, cannot be expected to provide the knowledge which would now be considered necessary; the tenure of land is intimately connected with social custom and economic conditions, and its real character can only be ascertained by an inquiry sufficiently comprehensive to take into account all the conditions which have determined its development. Experience elsewhere has shown that one of the most effective methods of study is that which takes a sufficient number of plots of land as the basis of inquiry, and by recording all the ascertainable changes in the use of each plot gradually builds up a knowledge of the law which determines the local system of tenures.⁵ That approach has the further advantage that it enables tenures to be described in terms which express African conceptions of land custom and avoids the danger, which appears to be inherent in the system of questionnaires, that inquiry may be directed to ascertain the nature of tenures in the terms of modern European conceptions of land-holding. It is no doubt true that this method of inquiry increases the difficulty of making a logical analysis of principles, such as seems to be desired in some of the French studies on the subject; but it is a difficulty which must be recognized as inevitable in all inquiries into African custom. The information which can be gained from a study of judicial decisions, though by no means

without its use, has a limited value in any comprehensive inquiry into land custom; the decision of the native court will no doubt reflect correctly the prevailing sentiment as to the custom by which the issue before it should be decided, but the court is seldom equipped to give a statement of principle; the European court, on the other hand, is largely dependent upon the evidence produced by the parties and the opinion of a selected body of assessors. It would, perhaps, be true to say that judicial proceedings are calculated to afford useful evidence as to the application of custom, rather than the material on which a comprehensive statement of its character can be built up.

(c) *Changes in Land Tenure*

Important, however, as it is that the traditional systems of native land tenure should be adequately studied, it is equally necessary to investigate the changes to which these systems are being subjected by modern conditions. Inquiry into such changes presupposes some knowledge of the traditional systems: without such knowledge, the significance of the changes cannot be fully appreciated.¹ The influences making for change are twofold; first, those due to economic circumstances, such as the increasing pressure of population, new methods of cultivation, or growth of a marketing economy; and second, those due more directly to the action of administrations in introducing forms of tenure based on European conceptions. It is not easy to estimate the relative importance of these factors, but their effect may be illustrated by reference to certain areas where their operation can most readily be recognized.

South Africa. In the Union the customary tenure is still strongly established in the native reserves outside the Cape Province, though modified in some respects in Natal by the operation of regulations, such as those issued under the Native Administration Act of 1927, dealing with the control to be exercised over chiefs and headmen in regard to distribution of land.² There is evidence

¹ The need for a careful study of such changes is emphasized in a paragraph on pp. 7-8 of *A Five Year Plan of Research*, published as Memorandum IX by the International Institute of African Languages and Cultures.

² H. Rogers, *op. cit.*, 1933, pp. 125 ff.

of a tendency in some areas to demarcate family holdings, and also to subdivide them; the Witzieshoek reserve in the Free State appears to afford an extreme example of this process.¹ The Natal Commission of 1881-2 recommended that natives not exempted from native law should be allowed to purchase land on individual freehold tenure,² and the Commission of 1903-5 considered that natives should be given an opportunity of owning land in individual tenure but in demarcated areas only.³ It is, however, only in the Cape Province that the movement for the introduction of individual title has attained real significance. The earliest instance in that province was the settlement in 1849 of the loyal Fingoes in the Smith-Calderwood locations of Victoria East, where individual holdings were allotted on an annual quit rent.⁴ The Cape Native Locations Act of 1879 further extended this principle, and the Native Laws and Customs Commission of 1883 recommended that where natives desired to acquire individual titles in place of their customary rights, these should be conceded. These measures prepared the ground for the Glen Grey Act of 1894, a measure which is as important in the history of the land systems of Africa as it is in that of native administration.⁵

The objective of the Glen Grey Act was wider than the regulation of land settlement, but to many at least of its supporters it represented a genuine contribution to the civilization of the Bantu by extending to him the benefits of individual property.⁶ It provided for the survey of allotments of a standard size of eight acres, the spare land in each location being treated as grazing commonage. The allotments were to be held on a perpetual quit rent, the grant of freehold being avoided in order that the tenure might be subjected to conditions. To preserve the allotment from division, succession was to be by primogeniture as determined by native custom; transfer was made subject to the government's consent, and rights were liable to forfeiture for rebellion, stocktheft, or failure to make beneficial use of the land. The principle of primo-

geniture was maintained by the Native Administration Act of 1927. The Glen Grey Act was extended to the Transkeian Territories by a series of proclamations commencing in 1898, but in only seven of the twenty-seven districts have lands been surveyed into allotments on the lines contemplated in the original Act. In twenty districts of the Transkei the land is accordingly still held on a modified communal tenure, fresh allotments of land required for occupation being roughly demarcated on the authority of the Native Commissioner by native subordinates assisted by headmen. The decision to limit survey to the seven districts was due mainly to the cost to the native; but it cannot be said that the condition of the surveyed districts is so noticeably superior to that of other districts as to furnish a strong argument for an extension of the system. Restrictions regarding subdivisions were to some extent relaxed by Proclamation no. 300 of 1913 as regards the Transkei, and in the Ciskei by no. 66 of 1936.

The success of the Act as an experiment in individualization has been prejudiced by circumstances. Though undue subdivision is nominally prevented, the density of population is such as to deprive the regulation of most of its effect, since the landless members of the family continue to squat on the allotments; there were in the Glen Grey district, in 1929, 4,000 adults paying tax for whom allotments were not available; in the seven surveyed districts it was estimated that 11,000 married hut-owners had no arable plots. Further, it is doubtful whether with their present methods of cultivation the holders can support themselves on their allotments; the rural economy is largely dependent on the keeping of stock, and the numbers maintained are such that pasture is rapidly exhausted and soil in consequence eroded. It has not been possible for the allotment-holder to become in any real sense a farmer; the Native Economic Commission, indeed, recommended that the restriction on the size of holdings should be relaxed, the maximum suggested being 105 acres.¹ The conditions in the Transkei have not been such as to offer to the native any clear evidence that a more intensive cultivation would yield an enhanced return as compared with stock-raising, and the value of the right of transfer is reduced by the fact that the social organization allows other

¹ U.G. 22, 1932, *op. cit.*, paras. 140-52.

members of the community to secure the advantages of common grazing without acquiring an allotment. At all events, numerous allotments have been cancelled for failure of beneficial occupation.¹

The system of the unsurveyed districts, with its rough allotment by headmen of plots which carry only an occupancy right, has been held by many observers to have an elasticity which is on the whole better suited to the present conditions of the Transkei. It has, indeed, been suggested with some truth that the Glen Grey experiment missed out an essential stage in evolution to the individual title—namely, the allotment under appropriate conditions of plots large enough to accommodate extended family groups—and some have felt that even now it would be useful to allow kindred groups to amalgamate.² Elsewhere in the Union the grant to natives of a free right to dispose of holdings held by them in individual tenure has been attended with unfortunate results. The lands which the Griqua were permitted to retain under the old treaties were extensively alienated by them,³ and the small Moroka ward in the Free State has a somewhat similar record. The titles conferred by Moroka were confirmed when the Free State annexed his territory in 1884, but the holders were debarred from alienating except to relatives, a condition which was modified when the Moroka Ward Land Relief Act of 1924 allowed transfer to other members of the Barolong tribe with the sanction of the administration. But in the absence of regulations against mortgage many of the original ninety-five farms fell into the hands of Europeans, and most of the remainder are heavily burdened with bonds.⁴

The general position throughout the Union with regard to the purchase of land held by Europeans has already been explained.⁵ It was shown that native acquisition of title by purchase was allowed under various local conditions, except in the Free State, up to 1913; between that year and 1936 it was restricted except in the Cape Province. The Land Act of 1913 laid down that lands could not be acquired by natives outside native areas except with the Governor-General's approval. As this approval is in practice given only in exceptional circumstances, natives are virtually de-

⁵ See above p. 721.

barred from acquiring lands except in the 'released' areas.¹ In 1935 it was estimated that natives held in individual title 1,393,428 acres in 'released' areas, and 645,432 acres in European areas; they were distributed between the provinces as follows: Cape, 124,873 acres in 'released' and 125,076 in European areas; Natal, 188,878 acres and 190,120 acres; Free State, 93,388 acres and 23,904 acres; Transvaal, 986,289 acres and 306,332 acres. As regards the Transvaal it may be noted that in 1905 the Transvaal Supreme Court ruled that natives could acquire land in individual title,² but the Land Act of 1913 has virtually restricted acquisition to the 'released' areas. Transfers of freehold title already held by natives outside scheduled and released areas are regulated by European law. The greater part of the land in the released areas will be held by the Native Land Trust for leasing or renting to natives who will hold it on their customary tenure; in exceptional cases natives will be allowed to purchase land in individual title from the Trust or from Europeans in these areas.

Southern Rhodesia. In Southern Rhodesia the custom in regard to native lands seems to have been little affected, but it is of some importance that the powers normally exercised by chiefs in the allocation of land are withdrawn in favour of the Native Commissioners.³ Considerable interest attaches to the introduction of new forms of tenure by administrative action. The 'Cape Clause' reproduced in the charter had given natives the right to acquire and hold land on the same terms as Europeans,⁴ and though the administration did not allow natives to make purchases from Crown lands, a certain area was acquired by them from Europeans, estimated in 1923 to be about 100,000 acres.⁵ The Land Apportionment Act of 1930 has now set aside an area of 7,464,600 acres in which purchases can be made through the Native Land Board; title will not be in fee simple, but held on conditions; thus it can be forfeited if land is not beneficially occupied; transfer and mortgage will be invalid without the board's consent, and in order to prevent undue subdivision, both testamentary and intestate succession have also been subjected to its control.⁶ By December

⁶ Native Wills Act, 1933, sect. 8.

1936 natives had taken up a total of 552 holdings, comprising an area of 188,182 acres, but part of this was acquired by groups; it is stated that natives have been prompt in payment of their instalments. Under the system introduced in 1932, land can be leased by natives at the ordinary rate of rent for Crown land, with an addition representing instalments of purchase. Southern Rhodesia has, therefore, made a substantial provision for the acquisition of individual title by natives who desire to live outside tribal conditions.

Northern Rhodesia. In Northern Rhodesia changes in native customary practice seem to be shown chiefly in the closer demarcation of family holdings in the more congested reserves and in the southern province, where intensive ploughing of corn lands is evolving a system of peasant farming. Action taken by the administration in the direction of granting individual title has so far been confined to the leasing of plots of about 5 to 10 acres in extent on Crown land in the vicinity of certain townships on the railway line and in the copperbelt. These were originally intended as residential plots, but are used as market gardens. The soil is rapidly being exhausted, and if the system is to be maintained or extended, adjustments will be necessary in rents, which are at present often out of proportion to the value of the holdings; and advice on working the land also appears to be required.¹ A few natives lease small farms in the southern province, parts of which they sub-let to other natives.

East Africa. In Nyasaland it is clear that economic conditions have begun to react on custom in the more congested areas; thus a practice of transfer was recorded as existing in 1920 in Marimba and West Nyasa districts.² In Tanganyika the results of population increase and the stabilization of cultivation have been seen in the more permanent demarcation of occupied lands in closely cultivated areas, such as Ukerewe Island and some regions on the shores of Lake Victoria, or in the enclosing of the vihamba of the Chaga on the volcanic lands on Kilimanjaro. It is stated that even grazing lands have at times been delimited, as in the case of the ngitili lands of the Sukuma. Occupied holdings are stated to be subjected to close subdivision near Mwanza. Transfer of the

¹ *Report*, op. cit., Colonial 145, 1938, p. 69.

² *Report*, op. cit., 1921, p. 5.

special form of nyarubanja title existing in Bukoba district, a survival of fiefs similar to those prevailing in Bunyoro in Uganda, is registered by the native authority, and among the Chaga a native authority regulation recognizes transfers of vihamba made with the authority of the chief. The conditions in the coastal area differ in a marked degree from those inland; it has been recognized in these districts that individual titles can be acquired by prescription, and tenure is regulated on a system adapted from the Moslem law. In the Lindi district, for example, increasing use is made of the courts to record land transactions; these for the most part concern land which has acquired a permanent value from the planting of coco-nut and fruit trees.

As regards the steps taken by the Tanganyika Government to deal with the question of land rights, it has been explained¹ that the land law makes the existence of a title dependent on grant or recognition by government, and that apart from the maintenance of freeholds derived from the German Government, title now takes the form of a right of occupancy granted by the Crown. This right, as has been shown, is held to include the title of a native or native community lawfully using or occupying land in accordance with native law and custom. While this provision gives ample security to natives in the occupation of their lands, an individual title can only be secured by the grant of a right of occupancy, and a wide concession of such titles over native lands, even if accepted as desirable in point of policy, could not be made effective without a land survey and the provision of machinery for registration. So far natives appear to have applied only for right of occupancy in small parcels of Crown land in the vicinity of townships, on which rent becomes payable. The tenure on peasant farms such as those at Kingolwira and Nyamahona, in which the administration is endeavouring to improve farming by the creation of 'peasant holdings',² does not seem to have received any formal legal definition.

In certain of the Kenya reserves the density of population, and the progress made in growing cash crops, has produced a marked effect on land custom. The Kikuyu, in particular, afford an interesting example of the modification of custom under new condi-

¹ See above, p. 764.

² See Chap. XIII, p. 969.

tions. The claim of the Kiambu Kikuyu that they had acquired a part of their area by purchase from the Dorobo is, perhaps, unique of its kind in East Africa. The true nature of the transaction is debatable; it is comprehensively described by the Land Commission of 1933¹ as a process partly of alliance and partnership, partly of adoption and absorption, partly of payment, and largely of force and chicanery; but for the present purpose its chief interest lies in the fact that in the Kiambu district the Kikuyu, on the strength of the tradition of acquisition from the Dorobo, now follow a recognized practice of selling holdings, and that a meeting of the combined Kikuyu native councils has laid down conditions regulating the recognition of sale. There is a certain tendency on the part of other sections to adopt the practice of the Kiambu district, though at present the general rule that pledges on land are redeemable is followed.

Kikuyu custom presents another interesting feature in the development of the githaka system.² It originated in the process by which families took possession of land in a country sharply divided by streams; on the lands on the ridges between the valleys, groups of families acquired rights over which control was not exercised by the clan authority. The usufruct of the land was divisible, subject to the supervision of the head of the group of families known as Muramati or warden. It would seem, however, that in some of the Kikuyu areas this control has, in modern conditions, become purely nominal, and rights have begun to vest in a single individual or sometimes in a man and his brothers rather than in the group occupying a ridge. The Kikuyu Land Tenure Committee of 1929³ stated with regard to the Kiambu district: 'If the present tendencies were to continue unchecked for another generation, it may be conjectured that in this area the Githaka would by that time have given place to the small holding as the unit of land tenure.' The introduction of the plough and the consequent increase of the area cultivable by the family unit is said to have led in the same tribe to the resumption of areas formerly pledged to outsiders.

The practice of sale appears to be gaining ground among some

¹ *Report*, op. cit., para. 285.

² *Report*, op. cit., 1929.

³ *Ibid.*, chap. i, para. 25.

of the other tribes in Kenya: it is said, for instance, to occur among the Teita. The permanent demarcation of family holdings is becoming common in the Kiambu district and there are cases where even grazing areas are roughly delimited, as in the kiseso system of Kamba. In the more congested areas an increasing number of holdings are subdivided; figures cannot easily be given, but an extreme instance is that at Maragoli in the Kavirondo reserve, where the average holding is now stated to be between half and a quarter of an acre. In the Machakos reserve there is the same tendency as in the Kiambu district to convert family into individual holdings; here progressive natives have built permanent houses and have used ploughs to cultivate comparatively large areas of land. The position in the coastal districts is exceptional, since here, as in the corresponding areas of Tanganyika, the customary law came under Arab influences, and individual rights were well recognized. But the titles to land are in a state of some confusion. In 1908 a Land Titles Ordinance was enacted, and from that date till 1922 inquiries into titles were carried out by a special Recorder; 21,700 claims were examined and 10,000 titles issued giving an indefeasible title subject to an appeal to the Supreme Court. Some 4,000 of these were never taken up, mainly because the cost would have been more than the claims were worth. The question has again formed the subject of a special inquiry, as suggested by the Land Commission of 1932; meanwhile, the matter has assumed a new importance in view of attempts made by companies to acquire mining concessions. So far as regards the effect of action taken by the state in introducing European forms of tenure, it may be noted that Kenya, apart from the recognition given to titles in the coastal lands, has as yet made no provision for the acquisition of proprietary title by natives, though some proposals on the subject were put forward in 1928. Reference has already been made¹ to the recommendation of the Land Commission of 1932 that 939 square miles be reserved for natives who find difficulty in settling in the reserves, such as returned labour tenants or natives removed from urban areas. The title would be leasehold, not freehold, and the leases would be either on individual or group tenure or given to corporate bodies; they

¹ See above, p. 750.

would be subject to the condition of indivisibility on succession; disposal or encumbrance would be invalid without the sanction of the administration. Legislation to give effect to these proposals has not yet been introduced.

In Uganda the most conspicuous developments have been seen in the results of the grant of the proprietary right in the Buganda Mailo lands, of which some account has already been given.¹ The Agreement of 1900 was a political measure, and, unlike the Glen Grey Act, was not a conscious experiment in the individualizing of tenures. It spoke of the lands of the Kabaka, and those to be allotted to the chiefs, as their 'private property' or 'estates', and this undoubtedly involved the recognition of some form of proprietary right, though this, as has been shown, was in itself alien to the system under which the chiefs had held their lands. The precise nature of the title to be conferred was determined on the recommendations of a commission appointed in 1906-7;² it was in most of its features that of freehold, regulated by a system of survey and registration, begun in 1904 and only lately completed. The grant of a title of this type was largely dictated by the desire to implement fully the terms of the Agreement, and there is no doubt that the administration was also influenced by the apprehensions of the Buganda chiefs lest their lands should be brought within the scope of the system of alienation of which Kenya was affording a conspicuous example. Had policy permitted it, some of the results which followed the grant of title might have been avoided if proprietorship had been qualified by limiting the power of transfer and prescribing the relations to be observed by the proprietor with the peasants occupying the land. Apart from the difficulties which arose in regard to the bataka lands, and the position of cultivators,³ the effect of the grant of estates to chiefs in proprietary right was to divorce landholding from the exercise of their political functions, upon which control over land had formerly depended. These functions now devolved on a new class of district chiefs, so that the possessors of Mailo lands acquired rights for which they rendered no service to the community, and as personal ties were broken with the passing of the first generation

¹ See above, pp. 760-3.

² Colonial, African 869, 1907, pp. 304-14.

³ See above, p. 762.

of landlords, and heirs succeeded who had no duties that brought them into close contact with their tenants, the relation of landlord and tenant began to be a purely commercial one.

The establishment of the Mailo system in Buganda was followed by requests for its extension to the Toro, Ankole, Bunyoro, and Busoga districts, but the government confined itself to the grant to the ruler and a few leading chiefs in Toro and Ankole of a limited area, to which they were entitled by agreements of 1900 and 1901 respectively, these grants being made as freeholds under the Crown Lands Ordinance of 1903. The question of the right to be granted to peasant cultivators in these four districts was investigated by a committee whose inquiries lasted from 1911 till 1920. The recommendations of this body tended towards the grant of the same type of proprietary rights as had been accorded to the Mailo owners of Buganda; but a realization of the difficulties caused by the grant of such a title in Buganda caused the administration to defer a decision. In his speech on the occasion of the completion of the Bunyoro Agreement of 1933, the Governor expressed a preference for securing the position of occupiers by legislation applicable to the whole country and not by individual agreements.

From 1923 to 1935 a series of draft ordinances have been prepared in an attempt to find a satisfactory form of legislation; the initial stages of discussion were still dominated by considerations based on the possible needs of alienation to Europeans for farms or plantations, and it was at one time proposed to delimit spheres for non-native and native occupation. As the demand for land by Europeans declined, attention was increasingly concentrated on the problem of finding a suitable type of tenure for native peasant occupiers; but no final decision has yet been taken. Meanwhile, there remains in force in certain districts the system, initiated as the result of the Toro Grievances Report of 1926, under which certificates of occupancy can be granted to cultivators, while reserving the property right to the Crown. These certificates give to the cultivator an undisturbed tenure so long as he occupies the land; further, he has the right of testamentary disposition and the right to dispose of trees, buildings, and crops when the occupancy is terminated. So far, little desire to obtain this certificate has been in evidence, partly because there has not been the pres-

sure from landlords which made tenants on the Buganda Mailo lands anxious to secure freehold. With the extension of commercial crops this demand may grow; it appears likely that the ultimate decision regarding the rights to be granted to cultivators may embrace a general provision of this nature.

Nigeria. In the British West African colonies modifications of native custom in regard to land are more clearly marked than in those of the East. In the northern provinces of Nigeria, as has already been observed,¹ conceptions based on Moslem law did not in practice lead to any considerable change in the original custom; the political authority of the emirs manifested itself chiefly in claiming an ultimate right of control over the land, and in the exercise of seignorial rights. The fiefs given out to Fulani leaders were administrative areas, and the right of the fief-holder to take a share of the taxation and the fact that estates were attached to certain offices, some of which are still held, were a means of rewarding political or military services; to this extent the system had many points of resemblance to that followed by the Mogul Emperors in India. The effect of economic developments is seen in the fact that family holdings are clearly delimited; the whole Hausa country is covered with small holdings, ranging from one to four acres. The tenure remains that of user only; but the transfer of this right, subject to the sanction of the emir, is now recognized by the native courts in Kano and Bornu. Such transactions are in addition subject to the law of the protectorate regulating transfers to 'alien' natives.² Kano presents an unusual feature in that the adoption of the principle of a tax based on the yield from land in six of its 'districts' has led to the survey and mapping of holdings by the native administration, the names of rightholders and transfers among them being regularly recorded.³ The land law now in force in Northern Nigeria, like that of Tanganyika, prescribes⁴ that an individual title can only be acquired in the form of a right of occupancy; few applications have, however, been made for such grants, and those mostly in regard to urban lands; nevertheless, it is clear that in the northern emirates an exclusive right of user, which has now lost most of the aspects of a communal

¹ See above, pp. 771 ff.

³ See Chap. X, p. 579.

⁴ See above, pp. 772-4.

right, is being gradually built up, beneath the ultimate right of the Crown.

In the southern provinces of Nigeria, where the land has not been declared subject to government control as in the north, changes in customary tenures have reached a stage which merits treatment in some detail. In 1924 it was stated officially that transfers of town land were freely made among the Egba, and that in Abeokuta, in particular, many transactions concerning such lands bore all the features of private ownership. The answers given to an official inquiry in 1928 showed that sales were frequent in Ibadan, though in theory they came under the control of the native council. At Abeokuta the right to alienate had by this date become so generally recognized that sales of farm land were advertised, as many as a hundred auctions being held in the year, and sales were recognized even among the hill tribes of Mamfe in the British Cameroons. Ward Price's inquiry into land rights in the Yoruba Provinces¹ showed that transfers were there fully recognized, at all events so far as concerned land broken up by individuals. A general practice had grown up in the lower parts of the southern provinces by which sales were recorded in documents of legal form, which were frequently registered. In 1924 the Egba Native Council made a proposal that where it was proved to their satisfaction and that of the Resident that an Egba stood personally possessed of real property in the town of Abeokuta, he should be at liberty to sell or mortgage it; outside the town he should be able to mortgage his crops, but not the land itself. The proposal gained the support of the administration, which expressed the view that the existing lack of facilities for transfer was restricting the legitimate use of credit based on land, but the matter did not go farther, partly because the proposed scheme would have permitted of transfers to non-natives as well as to natives. Miss M. M. Green's study² of Ibo land-tenure showed that while temporary transfers of land amounting to short-term leases were common, the sale of land was forbidden by native law and custom.

In 1926 the question was revived on a broader issue. It was urged by the Agricultural Department that the lack of means for securing an individual title was prejudicing the prospect of im-

¹ *Report*, op. cit., 1933.

² *Op. cit.*

provement in agricultural methods. The Lands Office pointed out that the customary system of tenures was breaking down in some of the southern districts; large numbers of unregulated transactions were taking place among natives, and everything pointed to the need of some provision for recognizing and recording titles. It emphasized the fact that the administration had so far touched only one aspect of the problem of transfer; the Native Lands Acquisition Ordinance had provided that no alien could occupy or hold land without the approval of government, and native authorities had been encouraged to make rules under the Native Courts Ordinance to prevent 'stranger' natives from occupying land without a certificate from the native authorities; but nothing had been done to legalize the growing practice of transferring lands among natives of Nigeria.

In the Residents' conference which discussed this question in 1929 and 1930 there was diversity of opinion: it was held by some that sale and mortgage were so alien to native law and custom that they should not be recognized; others objected that the extension of proprietary rights would prejudice the system of native authority administration; and others again, while admitting that custom was becoming modified and that transfers were taking place, held it to be inadvisable at that stage to do anything which would stabilize native rights in terms of the European law of property. There was a feeling that for the present it would be sufficient to give to native authorities the power to regulate sales and record rights, a process which would not only have the value of elasticity, but would recognize the position which certain of these authorities now occupied in legal control of transactions regarding lands. The government inclined to the latter view, but legal difficulties were found to stand in the way of framing rules under the Native Authority Ordinance, and a Bill which was drafted in 1933 to give the necessary powers to native authorities in the Yoruba Provinces also had to be dropped. The subsequent Registration of Titles Ordinance of 1935 provides for the issue of titles on application, and gives a title in terms of freehold and leasehold, but it will be confined in the first instance to Lagos Township, where these forms of tenure are well recognized and documents of transfer have been regularly registered. Lagos has the further advantage of a

complete survey. The extension of this measure to other areas will depend on the experience gained of registration of title in Lagos, and on observations made of the manner in which property rights shape themselves elsewhere.

In the Cameroons under British Mandate there are considerable sales of land to stranger natives in the south; in two divisions, Victoria and Kumba, strangers now outnumber the original inhabitants. Sales are now regulated by rules made under the ordinance regulating the disposal of land to strangers.¹

Gold Coast. In the Northern Territories of the Gold Coast there seems to be little evidence of mortgage or transfer, though in the more congested areas of Zuarungu or Navrongo the limits of family occupation are regularly demarcated. Here, as in the northern provinces of Nigeria, title is only granted in the form of a right of occupancy from the Crown. In the southern areas of the Gold Coast the movement towards the commercial use of land has reached a stage even more clearly marked than in the southern provinces of Nigeria. The wide use by the chiefs of their powers over 'stool' lands for the grant of concessions,² the growth of land values owing to the expansion in the export of cocoa, added to the spread of the practice of using English documentary forms of transfer, have created conditions in some of the colony districts which have been described as amounting to a virtual breaking up of the older usages in regard to land.³ To these influences must be added that of a judicial system which has brought large numbers of land cases on appeal up to the Supreme Court;⁴ the latter, though maintaining the customary rights of the family in succession to land, has tended to deal with transfers in terms of English law.

The result was on one occasion officially described as 'an exasperating uncertainty' in respect of titles to land,⁵ a description which no doubt referred mainly to the difficulties which government and mining interests had to face in ascertaining the title in lands acquired for public works or commercial purposes; but there is also evidence of a sense of insecurity among natives in

¹ *Laws of Nigeria*, cap. 85 (s. 24).

³ A. W. Cardinall, *op. cit.*, 1931, p. 68.

⁴ See above, pp. 775-7, also Chap. VII, p. 288, Chap. IX, pp. 465 ff.

⁵ *Address by the Governor to the Legislative Council*, 1929, p. 97.

regard to the conditions under which they occupy their lands, arising partly from the extent of the alienation of 'stool' lands by chiefs, partly from the difficulty in obtaining a legal title to lands transferred by one native to another. Litigation regarding land rights was said in 1926 to have become a curse of the country.¹ This aspect of the land problem has been considered by government at different times from 1922 onwards. The proposal first put forward for introducing a system of general registration of native titles was clearly premature; registration presupposes the existence of a law of property or at all events of sufficiently defined titles, and this condition did not exist. It was proposed to meet some part of the difficulty by the establishment of administrative land courts which should deal with land questions coming up from the native courts before they went on to the regular judicial tribunals,² but the proposal was not followed up.

It was believed at a subsequent stage that a basis for title could be found by giving legal recognition to prescription as applied to the occupation of native lands. The courts had accepted as a general principle that African custom did not recognize the acquisition of adverse title by long occupation; but there were, on the other hand, cases on record in which they had held that long occupation and the development of the land under economic crops could confer a valid title, and acting on this decision had allowed execution in cases where persons holding and developing 'stool' land for considerable periods had subsequently mortgaged it.³ An ordinance drafted in 1927⁴ to give legal recognition to prescription was opposed by the Gold Coast Provincial Councils and abandoned. More recently it has been contended, on the basis of a further ruling of the Supreme Court in much the same sense,⁵ that these decisions had the same effect in practice as a Statute of Limitations. Even, however, if these rulings could be admitted as adequate, there would still be no means of securing recognition of title other than by reference of each case separately to the courts. The time may not be ripe for attempting a general registration of titles; but there would appear to be an adequate basis

¹ *Report*, op. cit., Cmd. 2744, 1926, p. 147.

for an experiment in registration in such areas as Accra, Takoradi, or the Crown lands of Kumasi, or in areas where title has been validated under the Concessions Ordinance. Outside these areas it will not be possible to make further progress until the limits of 'stool' jurisdictions have been decided (preferably by administrative decision having legal validity), the powers of chiefs in disposal of 'stool' lands legally defined, and the nature of the right which can be acquired by virtue of the occupation of land has been defined by statute.

In Togoland under British Mandate considerable land sales are made by chiefs to strangers, who generally have some tribal relationship with the local people, and as much as £20 is frequently paid by them for a village plot on which to build a house.

The French Colonies. In the French territories changes in customary law seem to have been less extensive than in the British West African colonies.¹ There are, however, recognizable instances of developments in the direction of individual ownership. Thus in Senegal there is an established system of rental, which appears to be based on an original recognition of seignior, the payment being on a scale fixed by custom similar to that of the *zakkat* or Islamic tithe; this has a parallel in the similar rentals taken by Arab holders of land in Dikwa, British Cameroons. In the well-populated lands of Dschang in the French Cameroons, holdings are marked off with permanent boundaries,² and on the lower Sanaga river there have occurred cases where men of tribes living in the delta islands have purchased lands on the mainland, which they now claim to hold in individual right.³ The court at Yaounde in the Cameroons by a decision of 1935 practically accepted the principle of prescription by ruling that individual property could be recognized in land on which a house had been built or valuable trees planted. In French Togoland the leasing of land is a well-established practice, and it would seem that this is also the case in Dahomey and the Ivory Coast.

In their land system the French recognize two classes of rights—namely, the full title of proprietorship, and the customary rights existing under native law. The full title is obtained by the *im-*

¹ See L. Geismar, *op. cit.*

² *Rapport annuel au Conseil de la Société des Nations sur l'administration du Cameroun*, 1922, p. 46.

³ *Ibid.*, 1923, p. 50.

matriculation of lands acquired by the process of grant, concession, or purchase from the state, or by purchase from natives; the system, which applies to the French colonies but does not exist in the same form in France itself, was inspired by that first associated with the name of Sir Robert Torrens.¹ As the title when registered is indefeasible, in the sense that it is certified by the state against all third-party claims, it is granted only after full notice to other claimants and the examination of their claims by the Conservator of Property, contested cases being referred to the courts; the holder has then full rights of disposal in transactions of all kinds. In French West Africa the system was introduced by a Decree of July 24, 1906; registration was made compulsory in cases of alienation by the state or purchase of rights from natives by Europeans or *assimilés*; it was open to natives to seek *immatriculation* for property held or acquired by them. In Equatorial Africa the privilege of *immatriculation* of land was at first confined to Europeans and *assimilés*, but was extended to natives, with some limitations, by a Decree of December 12, 1920. It was introduced in French Togoland by a Decree of December 23, 1922, and in the French Cameroons by a Decree of July 22, 1932.² It is an important fact that the *immatriculation* of land renders it subject to the French civil code, as modified for use in the colony, in so far as concerns transfer, mortgage, or encumbrance, though it is still subject to native law in regard to succession.

The provision for the *immatriculation* of native property is part of a general policy which attaches great importance to processes tending to encourage the recognition of individual title in native land. Some reference has already been made to the influence of the judicial conception of property as an individual right, but individualization has been advocated equally on economic grounds. Not only have writers such as M. Leroy-Beaulieu³ emphasized this policy, but official reports have consistently put it forward as the objective of government. As the report on the colonial budget of 1910 put it, 'the system of individual ownership is incontestably

¹ See below, p. 876.

² A. Girault, *Principes de colonisation et de législation coloniale*, 1930, vol. iii, chap. xvi; P. Daresté, *Traité de droit colonial*, 1931, vol. ii, pp. 216-17; *Rapport annuel au Conseil de la Société des Nations sur l'administration du Cameroun*, 1934, pp. 91, 187.

³ *De la colonisation chez les peuples modernes*, 1908.

the one which is most favourable to production'.¹ Its advantages as affording a basis of credit have been freely pointed out to native leaders; thus the Governor of Togoland, speaking to the Lome Council of Notables in 1924, stated: 'Si vous désirez avoir de l'argent, il faut immatriculer vos terrains; vous pourrez ainsi obtenir des avances de la Banque.'² The opening to natives of the right of registering their lands by *immatriculation* was regarded as a step to 'voluntary individualization'. The progress made under the procedure of the 1906 decree was, however, disappointing; a commission appointed to investigate the matter in 1915 found that the total number of titles issued was 1,267, the majority being for urban property.

As a result of their recommendations a simpler process, that of the *constatation des droits fonciers des indigènes*, was introduced in French West Africa in a Decree of October 8, 1925, in French Togoland by that of August 24, 1926, and in the Cameroons by that of July 21, 1932; this last Decree supplemented in turn an earlier Decree of August 20, 1927, providing for the issue by district officers of *actes de notoriété*. Persons who seek a record of *constatation* approach the *Chef de Circonscription*, who, after publishing the demand locally, makes an inquiry from chiefs and notables, referring contested cases to the native tribunal, and finally delivers to the claimants a *livret foncier* describing the nature of their rights. This can be applied to family and collective as well as to individual rights; unlike *immatriculation* it does not create an indefeasible proprietary title, but is intended to secure the holder from dispossession by anything but judicial process, and has the advantage of leaving the land subject to native law. In the mandated territories, the production of this document is required before the alienation to a non-native of land registered under this procedure can receive administrative sanction. Applications for *constatation* have so far been confined mainly to areas such as the cocoa lands of the Ivory Coast and to urban properties; elsewhere it has not yet become widely popular among natives. In Togoland natives desiring title appear to belong mainly to the urban class, and prefer the full *immatriculation*, and applications under the simplified procedure are so rare that the administration has ceased to publish figures. In

² *Minutes of Session*, 1924.

the Cameroons, where the procedure under the Decree of 1932 only came into force in 1934, it had been applied by the end of 1935 in 67 cases, covering a total area of 1,067 hectares. In the whole of West Africa by 1934 it had been applied in 184 cases, covering 22,169 hectares. Under the *immatriculation* procedure the number of titles registered in French West Africa up to 1934 was 16,580, in the Cameroons 81, in Togoland 1,167.

The process of *immatriculation* is devised for the recognition of a system of proprietorship rather than one of usufruct; it is not adapted to the record of family or collective rights; the procedure is expensive, and from the native standpoint it has the defect that the prescribed method of publication in the *Journal Officiel* does not give adequate notice to other possible claimants. The latter fact furnished the grounds for the protests which were from time to time put forward against the system by the *Conseil Général* in Senegal. In the view of some classes of natives it has the further disadvantage that it subjects property rights to French law, and takes them out of the cognizance of the native courts. At one time its general application was opposed in some colonies by the authorities themselves, who hesitated to encourage the acquisition of clear title by natives in areas where the state itself might be likely to require land for public purposes or for alienation to Europeans; in that case property might have to be purchased which could otherwise have simply been regarded as *terre vacante*.¹ It is, however, correct to say that importance no longer seems to be attached to this consideration. Local policy now appears to recognize that resort to *immatriculation* on any considerable scale must await an expansion in the use of the powers of *constatation* as a method of establishing individual rights in holdings. The movement towards individualization has been to some extent assisted by another process—namely, the grant of concessions to natives from state lands; in urban areas in Senegal, Sudan, and the Upper Volta, where locations have specially been reserved for their occupation, the title granted is subject to the condition that there is no right of disposal to non-natives. In most cases the grant depends on the completion of development conditions.² Again, in the Sotuba canal

¹ *Journal Officiel*, 1922, p. 102.

colony about 5,000 persons have been given allotments in which they will acquire full rights at the end of a probation period of ten to fifteen years, and there will be a large development of this system when the major Niger Canal project comes into full operation.¹

The Belgian Congo. In the Belgian Congo it would seem that native land custom has so far been little subject to modification; for the most part there is little pressure of population, and the peasant cultivation of commercial crops is in an early stage of development. There is, however, in Belgium a school of thought which holds that economic advancement would best be secured by a system of peasant proprietorship; 'l'établissement du paysannat sous la forme la plus intégrale' was one of the policies recommended by King Leopold III in addressing the Senate in 1933, after his visit to the Congo. The practical implications of this proposal have been discussed by the Director of Agriculture in an article published in 1934.² A draft decree has been submitted by the Governor-General which would allow for native private ownership and the legal constitution of communal lands, but no more definite steps have yet been taken in this direction, and there is evidence that the administration is conscious of the effect which undue pressure might have in disintegrating native society. The Congo law attaches legal validity only to titles which have been secured by *enregistrement*; native land rights, not so secured, remain subject to native law and custom.³ Registration is effected by the *Conservateur des Titres Fonciers*, and is compulsory for all lands alienated by the state, or acquired by non-natives from natives; in the latter case the grant of title has to be approved by the administration. *Enregistrement*, though not carrying on its face the same guarantee as the French *immatriculation*, has much the same effect; in certain circumstances the state would appear to become responsible for a defect in the registration of encumbrances.⁴ It will be seen that the procedure applies only to proprietary titles acquired by non-natives; there appears to be no provision, such

¹ See Chap. XV, p. 1050.

⁴ Decree of Jan. 5, 1923.

as that existing in the French colonies, for enabling land in native occupation to be registered in proprietary title.

In Portuguese territory provision exists for granting title to natives on any land which they may have occupied outside the reserves, but the number of titles given is small. The Moçambique Company in 1932 introduced a system whereby holdings are offered to natives desirous of growing export crops; they are entitled to proprietorship after twenty years' occupation.

(d) A Review of Present Policies

From the foregoing account it will be clear that the problems connected with private rights in land fall into two categories. The first comprises those lands, relatively small in area, over which state action has given a title in European form and which, therefore, come under a law of property based on European law; the second comprises the great bulk of native lands, in which rights are still regulated by native custom. The former class has its own problems, to some of which reference has been made, as, for instance, whether the state shall recognize a freehold or a leasehold title in respect of lands which it alienates, or whether it shall insist on development conditions, or introduce terms which will secure it a share in the incremental value due to the general advance of the territory.¹ For the solution of problems of this nature ample precedents exist elsewhere. There is, on the other hand, little experience to guide those who have to deal with problems arising from the character of African land custom. In the description of the customary systems of land tenure prevailing in Africa it was suggested that they were typical of a stage of civilization at which there was little pressure of population on the land, and native life was organized mainly to satisfy subsistence needs. The question, however, arises whether, even where such conditions still prevail, the African system is calculated to give that amount of security and that measure of incentive to individual effort which is necessary if the best use is to be made of the land. It is obvious, again, that elsewhere large areas are being brought under new economic conditions, and that native land custom is already adjusting itself to the needs which they are creating. What steps have adminis-

¹ See above, p. 772.

trations taken to guide this process of adjustment? What system of rights in holding land do they themselves envisage as most suitable to native African conditions? In seeking an answer to these questions it is, perhaps, unnecessary to emphasize the consideration that the evolution of the most suitable form of land tenure is not merely an economic or a legal problem; among peoples whose circumstances do not provide any alternative means of livelihood, their relation to the land is not only the economic fact of most importance in their lives, but is closely integrated with all their social custom. It is this consideration that gives peculiar significance to the action taken by African administrations, either in guiding the natural process whereby land custom is adapting itself to new conditions, or in taking measures to substitute for it a new system of land rights.

It may, in the first place, be of advantage to analyse the tendency of the changes to which African land customs are now being subjected. If it has not been possible to describe them in full detail, the general picture is clear. There remain large areas in which traditional practice has been little affected; but even in some of these areas the rights of user are becoming more exclusive, in the sense that the clan at large is ceasing to have an interest in such lands, and the group or family occupying them have no interest in other clan lands. Other, but much smaller areas, mark a further stage when, owing to pressure of population and the growth of market crops, land begins to be given over to others for occupation; but leases are still often given in return for a gift or service of the traditional type, and the transaction is still dominated by the conception that land can only be pledged, and that a pledge is always redeemable. Finally, there are a few areas in which land values have now become so far commercialized that leases and sales on a cash basis are explicitly recognized; even here, however, rights are as a rule still viewed as vested in the family rather than the individual. It would, therefore, be correct to say that usufruct still remains the prevailing conception for the greater part of Africa; if usufruct has, in many cases, approached very closely to ownership, the latter only becomes patent when holders begin to exercise the right of transfer.

It is mainly when land has acquired an exchange value that

the authority exercised over it by chiefs acquires special significance. In some areas the traditional authority of chiefs over the distribution of tribal lands has developed into the exercise of a right of disposal to strangers, or a seigniorial right to take dues amounting to rentals. In certain British areas, the power of control over the taking of rent from stranger natives has been vested in the native authorities constituted as part of the machinery of indirect rule, and has therefore been brought within the field of statutory regulation; but elsewhere, as for instance in the Gold Coast, no such system has been applied, and the question of the disposal of rights in the communal lands is complicated by the fact that the actual seat of authority is sometimes obscure, and the extent to which the exercise of the right depends on the consent of elders or the like is undetermined. The disposal of lands to outsiders, even if it does not mean the dispossession of existing occupants, always involves the reduction of the margin of land available for distribution among members of the clan or tribe when the population increases, or lands under cultivation become exhausted. There is, in consequence, danger of a conflict between the rights of communal right-holders and those of chiefs exercising their political authority, and an increasing likelihood that the latter may, with the growth of commercialized conditions, assume the position of landlords. There are definite indications of this tendency in some of the French territories, and in the coastal areas of British West Africa.

There is nothing peculiar to Africa in the general direction which the evolution of land custom is taking; its adjustment in response to economic changes is a natural process which would occur independently of any action taken by the administration. It would, at first sight, appear that the state has two courses open to it: it may decide to allow the adjustment to take its natural course, or it may determine the course of development by regulations designed to produce that system of tenures which it considers most suitable to native landholding. But in practice, even where a government refrains from intervention in the process by so decisive a method as the introduction of legislation, the action of its administrative officers in reviewing the decisions of native courts, or in advising native administrations where they have been

given powers to regulate land tenure, must have an important influence upon the modification of custom; and where the judicial system provides that land cases shall come up on appeal from native courts to its statutory courts,¹ it is exercising a similar influence. In either case, therefore, great significance attaches to its conception of the form which native land tenures should ultimately take.

It will have been seen that, at the outset, the attention of governments in Africa tended to centre on questions connected with the acquisition of native lands by the state, or the regulation of alienation by natives to non-natives. In this respect, policy has now been sufficiently defined, even though it may not have been fully worked out in detail. There is less evidence of a considered approach to the question of the form which native rights in land should ultimately take. The French appear to have come nearest to a definite policy in so far as they look forward to the general expansion of a system of proprietary rights through the medium of *immatriculation*; the procedure of *constatation des droits fonciers indigènes* appears to be designed as a convenient preliminary to the more complete process. If so, then the influence of the *tribunaux indigènes*² will doubtless tend to mould native custom to the same end. The proprietary right thus established would be subject to the usages of European law, save in regard to succession, where it would follow native custom; and, though it is not possible to anticipate further policy in this respect, it is likely that the title will tend ultimately to be vested in the individual rather than the family. There is, at present, no indication that French policy will recognize the necessity for placing restrictions on the leasing of land held in full title, or on its use as security for credit. The state will doubtless continue to exercise the power to control alienation of native land to non-natives; but this would not modify the character of the title under which lands are held, nor the effect which its general use would have on tribal organization, or on native social life. Belgian policy is less clearly marked, and it is still doubtful if the individualization of property will be adopted as the policy of the government.

As regards the British territories, the Cape province has given

¹ See Chap. VII, p. 287, and Chap. XI, p. 431.

² See Chap. VII, p. 276.

the clearest indication of a desire to make a radical change in the direction of individualization. When the Cape Government introduced the Glen Grey system, it clearly contemplated a general system of individual holdings, which would not be held in full proprietary right, but would be heritable, and subject to state control of transfers. The system has not, however, been extended beyond areas in the Ciskei and Transkei.¹ It is unlikely that the passing of the 1936 Land Act will result in the purchase by natives of freehold land on any considerable scale in the 'released' areas; in the Union reserves, the tendency will be to exercise supervision over the occupation of land by natives to ensure that they make the best use of it, and native land custom will only be allowed to develop its own forms of tenure subject to these conditions. Sir Alan Pim, in discussing the benefits or otherwise of individualization of land tenure in Basutoland, considers that the safest line of advance would be to build on existing custom, to induce chiefs to promise protection to those who improve methods, and to aim ultimately at a system of registration of lands through chiefs.²

There is lacking any general statement of policy by the British Government in regard to the treatment of land tenures in their colonies and mandated areas. The Commission on Closer Union in East Africa³ confined itself to suggesting that existing systems of communal or clan cultivating rights could not be permanent, and that economic conditions would create a demand for some secure form of individual tenure. The Southern Rhodesia Commission of 1925,⁴ while of opinion that land tenure in the reserves must be regulated by native custom, would not perpetuate in the native purchase areas a system which they held to involve an uneconomic use of land. Native witnesses preferred freehold to leasehold, and the Commission recommended the introduction of individual tenure in the purchase areas, but thought that title should not be conferred till proof had been given of beneficial occupation; it should then be qualified by the condition that transfer should require sanction, and mortgage be allowed only

⁴ *Report*, paras. 67, 134, 253.

under stringent safeguards. The Kenya Land Commission¹ considered that native custom in the reserves should be guided in the direction of private tenure, proceeding through the group and family towards the individual holding.² The Committee on Kikuyu Land Tenure,³ in discussing the development of the githaka system, regarded the ultimate individualization of the rights as inevitable; they held, however, that the transition should be effected not only by regulation, but also by the action of the native authorities, under the guidance of their administrative officers. The report of the Committee throws an interesting light on the extent to which native land custom can be modified in Kenya by officers presiding over District Councils. In areas coming under indirect rule, influence would take the form of advice to native administrations. Reference has already been made to the course taken by the administrations of Uganda,⁴ Tanganyika,⁵ the Northern Provinces of Nigeria,⁶ and the Northern Territories of the Gold Coast.⁷ In the last three the policy adopted has been to allow native tenure to evolve without interference, subject to the radical right of the Crown; under their law, individual title can be obtained by application to the state, but it will take the form only of a right of occupancy, not of freehold. In the Southern Provinces of Nigeria⁸ and the Gold Coast⁹ there has been no formal decision as to the form which title in native lands should take; in the areas where commercial production is highly developed, economic conditions and judicial decisions have combined to create a form of proprietary right, but the administrations have shown some natural hesitation in accelerating this process by making any legal enactment which would amount to creating a proprietary title.

(e) *The Future Form of Title in Land*

All discussions on the subject agree as to the value of giving security to the occupier of land, and the further advantage of what is generally termed the individualization of tenures. It has been urged on different occasions that the extended system of rights,

¹ *Report*, op. cit., para. 650.

⁸ *Ibid.*, pp. 769 ff.

vested in the family or group, has proved in Africa to be an obstacle to improved agriculture; this applies not only to long-term improvements such as drainage, terracing of hill-sides, or planting of permanent crops such as cocoa and coffee, but also to cultivation designed to increase the output of subsistence crops. A Bechuanaland chief has been quoted as saying that 'in the communal system nobody who is willing to progress can have freedom to use his progressive ideas',¹ and in Basutoland chiefs are said to discourage measures which are essential for the preservation of land, such as the planting of trees or fencing of pasture lands, as implying a claim by the individual to rights over communal land.² Those who have had to deal with East African conditions have added the further argument that there is little incentive to natives to reduce their live-stock in order to prevent the wastage of pasture and consequent erosion, since nothing done by the individual will avail unless his neighbours take corresponding action; it is said again that the control of animal disease becomes additionally difficult under a system of communal grazing. It has finally been urged that, in some areas, the need has already begun to be felt for credit to finance the improvement of systems of cultivation, as well as for trading and minor industries, and that land, which is usually the sole security on which it can be raised, is not available for the purpose where a communal system of holding prevails. Each of these arguments is relevant in its own context; but it is necessary to analyse some of the general implications which, taken together, they would seem to suggest.

'Communal' or 'collective' tenures do not necessarily involve insecurity for the cultivator: in parts of Africa where cultivation is well established there is, in practice, little disturbance of occupation; insecurity on the part of the cultivating occupier is, indeed, an incident much more common to the relations of landlord and tenant than to the 'collective' system prevailing in Africa. The practice of shifting cultivation does not involve insecurity of tenure; and it would be premature to tie down cultivators to fixed areas until we can indicate to them with confidence agricultural methods which are likely to yield better returns.³ Again, the advantages

¹ M. L. Hodgson and W. G. Ballinger, *Bechuanaland Protectorate*, p. 54.

² L. Barnes, *The New Boer War*, 1932, p. 64.

³ See Chap. XIII, pp. 879 ff.

held to be inherent in 'individualization' are not necessarily to be secured only by attaching rights to the individual; there are some types of cultivation, such, for instance, as those which require frequent clearance of forest growth, which make the family or extended family the most suitable economic unit in cultivation. The question of rights over grazing commonages presents its own difficulties; the partition of grazing grounds into small units would be a bar to the adoption of that rotational use of pasture which many hold to be the best preventive of erosion in East African conditions.¹ It is clear, therefore, that there are many areas in which, at this stage, a policy of unqualified 'individualization' would involve economic disadvantages; and it is unnecessary to enlarge on the prejudice to the existing social structure of Africa which might result from the premature adoption of any policy extending exclusive rights in land.²

There are, on the other hand, certain areas in which a more definite advance in the direction of individualization is now justified both by economic and social conditions, and it becomes of importance to consider what form the process may most suitably take in such circumstances. Experience elsewhere abounds with illustrations of the far-reaching effects, often unforeseen by their authors, which have followed from the form taken by legislation defining the title to land. Thus, it was the form adopted in creating title which gave to Bengal, on the one hand, a rural economy of large landlords and a servient tenantry, and to parts of Northern India, on the other hand, a system of strong peasant proprietors. Any action taken in this matter becomes difficult of subsequent recall, because valuable interests settle round the form of title adopted. From what has been said in previous paragraphs, it will be realized that the power of regulating forms of title arises in three fields. The first comprises those areas in which the state has retained ultimate ownership in its own hands, such as the reserves in South and East Africa, or the areas in which it has asserted a full power of control over all lands over which it has not already given a definite title, as in Tanganyika, the Northern

¹ See Chap. XIII, p. 971, and Chap. XVI, p. 1067.

² See M. Hunter, 'The Effects of Contact with Europeans on the Status of Pondo Women', *Africa*, vol. vi, 1933, pp. 270, 271.

Provinces of Nigeria, or the Northern Territories of the Gold Coast. In such cases the state recognizes, defines, or creates subordinate rights by virtue of its own position as ultimate proprietor. Secondly, there is the field in which the state has asserted right of ownership only in vacant or unoccupied lands, as in the French or Belgian territories: in such areas, the process hitherto adopted for the grant of title has been to declare a particular unit of land to be vacant or 'unoccupied', and to confer a title from the state over what has thus become its own property. Thirdly, there is the field in which the state has claimed no rights over land, save those acquired by it through purchase or escheat, as in certain British west-coastal areas. Here the method followed will be the legal recognition of some form of title found to exist in practice, possibly modified in the process of definition.

The strong preference which was, at one time at all events, expressed in Europe for the proprietary title, was not based on any comparison between 'collective' or 'individualistic' systems. The belief in the 'magic of property' which, in Arthur Young's phrase, turned sand into gold, was based on a conviction of the superiority of the status of cultivator-owner over that of cultivator-tenant. If, in later years, the proprietary status generally has come under attack, it is not because it is no longer held to possess the virtue then believed to be inherent in it, but because proprietorship, in some circumstances, can give the holder a larger share of the incremental value acquired by his property than his contribution of capital or other effort justifies. In the present conditions of Africa, however, the problem of securing for the state a share in the incremental values of land, though not unimportant, is not one of the more pressing considerations which must determine the decision regarding the type of title to be recognized in native lands.¹ Other consequences of the creation of the proprietary title have greater significance at the present stage of economic development in native Africa. Those who regard its extension as unsuitable to native African conditions have urged that it has been found elsewhere to lead to the over-capitalization of land values, the misuse of the power of raising credit on land, the economic mischief of subdivision and fragmentation, and

¹ See above, p. 772.

the creation of a landlord régime. It is not suggested, even by those who most strongly oppose the creation of proprietary rights, that these results necessarily flow from the nature of the title itself; it is, however, felt that, given certain other conditions, the holding of land in proprietorship is favourable to their development.

It is necessary to examine in some detail the manner in which developments of this nature may be expected to occur in African conditions. There have certainly been instances in Africa in which the advantage taken of the negotiable value acquired by land in commercialized conditions has led to speculation and the over-capitalization of its value, with the double effect of accumulating land in the hands of those who do not themselves develop it, and of penalizing new-comers by forcing on them an undue burden of overhead charges. The European areas in the Union of South Africa afford many illustrations of this process; it would, however, be premature to suggest that, in the near future, conditions are likely to exist among Africans which may lead to speculation in native lands. The possible misuse of credit based on land is a matter of more immediate concern. The Native Economic Commission of 1930-2¹ remarked on the liability of the natives in the Union to misuse the power of borrowing on such lands as they have been allowed to hold in proprietary right, and a similar tendency has already been noted in certain parts of the Gold Coast and French West Africa. But, so far, conditions have not favoured the growth of money-lending; the general restrictions imposed on the sale of native land to non-natives, as well as the limitations which some territories have placed on the giving of credit to natives by non-natives, have militated against it.

Agricultural indebtedness has produced serious economic and social mischief in Egypt, and, as the report of the Indian Agricultural Commission² has shown, it has reached almost incredible proportions in some parts of India. It has been one of the less creditable features of British rule there that it failed to realize at an earlier stage the normal result of allowing the unrestricted use of the credit facilities which came into existence with the general

¹ *Report*, op. cit., paras. 166, 167.

² *Report of the Royal Commission on Agriculture in India*, Cmd. 3132, 1928, chap. xii.

registration of the proprietary title in land and the improvement in economic conditions. The credit available to the landowner has been used, in addition to its legitimate function of providing finance for farming purposes, for a great variety of other expenditure; and the heavy burden of mortgage-interest is not merely a bar to the improvement of agriculture, but has reduced large numbers of landholders to a state of economic serfdom which has, in turn, involved unfortunate social reactions.¹ The recent depression period called attention to the peculiar feature of agricultural debt, in that at periods when prices are suddenly depressed a debt-charge tends to trench on the margin of subsistence; it can then only be adjusted by special legislation, which is of a far more difficult character than that required for the adjustment of commercial debt. Some of the provincial governments in India have attempted to prevent the accumulation of agricultural debt by legislation limiting the period for which land can be mortgaged, or restricting the class of persons to whom it can be transferred, but these measures are easy neither to frame nor to execute; and whatever success they may attain, they will still leave a great burden of previous debt on the land. It stands to the credit of the land system of the Dutch East Indies, where titles are not transferable, that there is little agricultural indebtedness; the need for short-term loans for agricultural purposes seems to be adequately met by the State Credit Banks.

Another type of problem is created by the subdivision of holdings, and 'fragmentation', that is to say, the creation of holdings consisting of scattered units which results from the complex systems of inheritance recognized by Moslem and by some native law. A refusal to give legal recognition to the partition of holdings does not, as the experience of the Transkei has shown,² necessarily prevent the occupation of the holding by more persons than it can economically carry; until social conditions arise which enable the registered holder to remove other members of the family from the holding, they will continue to share it. Finally, the development of a system of landlord and tenant does not depend entirely on the recognition of the proprietary title: it can arise even where

¹ *The Central Banking Enquiry* (1930) put rural debt at £675,000,000.

² See above, p. 844.

the title is only one of occupancy, if the right-holder has at his command land surplus to his immediate requirements, or which it is more profitable to cultivate through others. As has been shown, in some areas the letting of land is already an established practice under native custom. But the existence of a proprietary title which is readily transferable undoubtedly tends to introduce new and less desirable relations between owner and tenant, and therefore tends to accelerate conditions under which these relations have to be regulated by legislation.

While considerations such as those referred to must always come into account, the decision as to the form which land titles should take must depend, in the last resort, on the type of rural economy which it is desired to establish. A rural economy in which the cultivator with an occupancy right is the predominant figure implies that the title normally recognized is one in which rights in the land are limited to the duration of its beneficial use, and are controlled as regards powers of transfer, though not as regards succession. The essence of a situation in which the proprietor predominates is the recognition of a right in land which is not limited by any condition as to beneficial occupation, and which the holder is free to encumber or alienate. In the conditions existing in many parts of Africa, a system of occupancy has many arguments in its favour. It constitutes less of a break with the traditional social structure and the prevailing system of cultivation; it avoids some of the dangers which flow from the unrestricted right of encumbering or transferring land; it does not prevent the eventual development of a proprietary régime, if economic conditions prove this to be desirable. The creation of this system would require the application of a different machinery in each of the fields described above.¹ In areas where the Crown retains the ultimate proprietary right over all lands it can be effected by direct state action; it is indeed already implicit in the type of right of occupancy in force in Tanganyika, the Northern Provinces of Nigeria, or the Northern Territories of the Gold Coast. In areas of the second type, notably those coming under French and Belgian law, the procedure by which registration of proprietorship² is now effected could without difficulty be em-

¹ See above, pp. 870-1.

² *Ibid.*, pp. 858 ff.

ployed for the grant of the occupancy right in cases where the state gives a title to natives over lands which it has classified as vacant or unoccupied; but it would logically require a new provision of law to give a title of occupancy where lands could not be brought under that description. In the third class of areas, such as the southern part of the Gold Coast or the Southern Provinces of Nigeria, the situation is more complicated. In some districts custom has gone far in the direction of the creation of a proprietary right vesting in the family; on the other hand, the chiefs have on occasion, as for instance during the discussions on the Land Bill of 1897,¹ shown themselves opposed to any legislation which, by recognizing rights acquired by prescription or long occupation, would curtail their authority over the disposal of land. It has been suggested that a solution of this problem might be found in legislation authorizing the chiefs to collect a seigniority due in return for their recognition of prescriptive rights, but it is likely that in the Gold Coast a revival of seigniority rights would meet with much opposition, as also would be the case in the Southern Provinces of Nigeria, where much occupied land is family land over which the seigniorial rights of chiefs are shadowy.² In any case, a legal definition of the chiefs' powers must obviously precede legislation creating or defining title in native lands.

As has already been remarked, the legal recognition of an individualized form of holding in native lands can at present apply only to a restricted area. Even in that area there is some danger in pressing the formal creation of title, lest it should cast doubt on the validity of possession elsewhere held on customary tenure; it is equally important to avoid a disturbance of social conditions by too ready acceptance of the desire of a certain section to acquire individual rights. Finally, there are areas in which caution may be necessary in view of native fears that the title may be used as a basis of taxation; in the earlier days of Indian land settlement many persons refused for this reason to have their title recorded, and in Palestine all records were for long vitiated for the same cause. The motives which prompt natives to acquire individual title, in the name of either a single person or a family, may be twofold. The desire may arise in a feeling that separate rights have

¹ See above, p. 776.

² H. L. Ward Price, *op. cit.*, 1933.

been established by custom, and that, in order to allow the land to be used to the greatest advantage, they should be confirmed by law; or it may arise simply from the need of securing the family holding from trespass, either by other cultivators or by the cattle of the community. The latter need, however, can be met, as has been shown in Kiambu and elsewhere, by encouraging the practice of constructing permanent boundaries, and of securing respect for them by influencing the native tribunals to penalize trespass. That process is, indeed, an initial and necessary step in the formal creation of individualized rights; the community, in effect, establishes its own rights, and subsequent recognition of title merely gives legal form to an acknowledged fact.

(f) *The Machinery for Recording Title*

In approaching this series of problems, administrations will be confronted not only by the need for deciding whether an individualized title is desirable, but by the need for providing a machinery for making title effective. A title can be secure, even though its only sanction be custom, so long as it is generally acknowledged and respected; but legal security against attack or disturbance can most effectively be guaranteed by registration, and this, in turn, involves a preliminary process of inquiry into the facts on which the title is claimed, and some process of survey for recording the area and boundaries of the land over which title is sought. Registration has hitherto been viewed mainly as a means of securing the possession of alienated lands; this has implied the grant of title in the clearest possible form, carrying a security which makes the property readily negotiable or available for the purpose of raising credit. For this reason, many administrations have, in granting freehold rights, accepted the principle that registration should guarantee an indefeasible title. The system by which they have been inspired was introduced by Sir Robert Torrens in South Australia about 1858 and subsequently adopted in Fiji in 1876 and New Zealand in 1885; it has had a wide extension elsewhere. Its essential feature was that it took the unit of land as the basis of record; rights were registered as attaching to the unit of land and not to the person, and it was, therefore, a measure of great convenience in early colonial conditions, which demanded a simpler

system of record than was then available under the European method, which treated rights as attaching primarily to the person. That the title recorded was indefeasible, and was guaranteed by the state against attack by third parties, was equally an advantage in those conditions, and was rendered the easier by the fact that the early colonial titles were derived from the Crown. While, however, there is little difficulty in recording and granting an indefeasible title in lands directly derived from the Crown, the process becomes more difficult where claims founded on custom or prescription have to be determined; an elaborate inquiry is necessarily required before the state can take the responsibility of guaranteeing the title which it registers.

It is essential that any system of registration, to be effective, must also provide the machinery for the ready record of day-to-day mutations on account of succession or otherwise, and such machinery takes an expensive form where the title registered is indefeasible. Further, indefeasibility of title is of lesser importance where the commercial value of land is not a primary concern. It is, therefore, a matter for consideration whether, in African conditions, it would not be preferable to adopt the alternative system under which a presumptive title only is recorded. That is the method in force in recording land titles in India; the title recorded holds good until questioned in the courts, when the burden of proof is on those who seek to contest it. Experience, however, shows that the great majority of recorded titles are never attacked, and an uncontested title acquires in time a high evidential value; it can, indeed, after a suitable period be given the legal value of prescription. Finally, where registration carries only a presumptive value, the process of inquiry before the record is made can be entrusted to a far less expert agency, and the local machinery for recording the mutations due to succession or the like is of a relatively simple character.

As has been remarked, registration of titles, to be effective, must be accompanied by some form of land survey. Where, however, the procedure of recording a presumptive title is in force, the survey can be of a simpler character than where registration confers an indefeasible title. It has already been suggested that the grant of individual title in Africa must be confined, in the first

instance, to areas where economic and social conditions render this advisable; and, even in such areas, neither the recording of title nor a land survey can be profitably undertaken until individual rights are generally recognized by the people, and the boundaries of holdings are clearly set out. The example of India, or, to take another instance, Borneo, shows that in these circumstances a plane-table field survey conducted by a subordinate and relatively inexpert agency gives sufficiently accurate results for such mapping as is required; it will be recalled that a purely African agency is at present carrying out such a survey in certain districts of the Kano emirate. It is an additional advantage, as experience has often shown, if such a field survey can be carried out within triangulation points established by expert surveyors. If a system of record of this type is to be successful, it is advisable that it should remain under government control; there are obvious dangers in the procedure proposed in certain parts of Africa, in which registration of titles would be left in the hands of native administrations.

CHAPTER XIII

AGRICULTURE

I. INTRODUCTION

(a) *The Basic Methods of Native Agriculture*

NATIVE agriculture¹ generally took the form of the shifting cultivation of subsistence crops, and the problems which arise to-day are mainly due to the changes forced on this system by the restriction of land, the stabilization of populations, the absence of large sections of the male population for long periods to earn wages, and the extension of cultivation in order to produce crops for sale.

Shifting cultivation has been described in a previous chapter as less a device of barbarism than a concession to the character of the soil.² The ground is used for as many years as it remains fertile, usually three or four years, and is allowed to revert to bush again until it has regained its fertility or until it is again required for use. Where forest land is available it is usually preferred for cultivation to secondary bush. In Northern Rhodesia, for example, the branches are lopped, carried to preserve the leaves, and laid in piles and burnt to form thick patches of ash, and in this process the whole country-side is often burnt. A newly burnt garden has been shown to contain more phosphate than an unburnt one. The amount of potash is also increased, and the reaction of the soil is changed from slightly acid to slightly alkaline.³ The effect of the burn soon wears off and a move to another forest area is then made. This type of cultivation (*chitemene*) is the most wasteful, but, as experience has taught the African that burnt forest land is particularly suited to the staple crop of small millets, it is practised throughout the forest areas of Africa, and in some areas all high

¹ As the economic questions arising out of the industries of agricultural and animal husbandry and the facilities provided for marketing are dealt with in subsequent chapters, the present chapter is confined to some discussion of the main features of African and European crops and herds and of the measures taken for their improvement.

² See Chap. I, p. 1.

³ *Report on the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, p. 221. See also Chap. XVI, p. 1077.

forest has already disappeared.¹ In non-forest areas shifting cultivation has been described as a system of rotational 'bush fallows'.² Native cultivation often takes the form of 'mounding', in which weeds and trash are laid as a foundation, and which is said to be based on sound principles. These systems require large operating areas: and it is estimated that sometimes twenty years is necessary for the woodlands to regenerate.

It is an error to suppose that tropical conditions in Africa imply exuberant vegetation and rich soil.³ Save for some exceptions, limited in area, the soil throughout that part of Africa with which we are now concerned is generally poor, and soils of the arid and semi-arid regions, which make up perhaps half the total area of the continent, have little humus. In addition one or more of the elements essential for plant growth, notably calcium and phosphorus, are insufficient over wide areas, and in arid conditions 'brak' or 'alkali', usually sodium salts, form layers which are toxic to plant growth. The continuance of shifting cultivation, or its replacement by a stabilized form of peasant farming, thus depends on the introduction of systems of manuring which will both maintain fertility and also suit native conditions of life and labour, and it is clear that the first step towards the improvement of a system, which is in many areas becoming unsuited to modern conditions of African life, is the study of African methods of cultivation, and an appreciation of the effect of such methods on soil productivity. In Africa, where the more fertile soils have been discovered and developed, the value of soil surveys lies not so much in their immediate practical application as in the collection of data which will be of importance in assisting in the solution of this fundamental problem of African agriculture.

Native agriculture varies considerably in method and in crops according to the nature of the country, the possession or otherwise of stock, and the customs of the tribe in regard to food; but everywhere it is based on a simple economy in which groups of persons co-operate in a system of mutual obligations to produce the necessities of life. The duties of collaboration are divided between the

¹ See Chap. XIV, p. 985.

² O. T. Faulkner and J. R. Mackie, *West African Agriculture*, 1933, p. 44.

³ E. B. Worthington, *Science in Africa*, 1938, chap. v.

members of the household, recognized tasks belonging to the sphere of men, women, and children. The African tradition of cultivation, although empiric, teaches methods of rotation of crops, of usage of soils, and means of fertilization and even sometimes anti-erosion measures, which, though they may not be suited to modern demands on the soil, are often well adapted to the prevailing conditions of labour and climate.¹ The implements of cultivation are the hoe and axe, wielded with skill and effect. The months are marked by a routine of clearing bush or tree cutting, fertilizing, sowing of crops, fencing, and harvesting, which forms the most important activity of tribal life. Journeys are only undertaken during a period when the fields may safely be left; hunting, beer drinking, dancing, and courting are fitted in among agricultural duties. The character of the marriage relationship in various tribes and the general status of women in the community is closely related to the share which they take in the provision of food. Thus in purely pastoral tribes women exercise relatively less influence than among agricultural peoples, where the heavy work they perform is a measure of their importance in the economic system, and where they are often able to acquire property of their own by marketing crops. The agricultural system is also closely linked with the position of the political authority from which in theory every member of the community derives his right to land cultivation. In many cases the chief is responsible for carrying out regular ceremonies on which it is believed the success of cultivation depends, and sometimes for rain making in times of drought. His own fields are usually cultivated with the assistance of his domestic circle, but to enable him to carry out the duties of chiefly hospitality, his grain bins are filled by offerings of grain from his subjects' gardens or by communal labour in special gardens at his capital.²

In some areas shifting cultivation necessitates the continual removal of villages, which are often mere garden shelters. If they are more permanent and cultivation is of necessity extended to distant lands, the population moves to these gardens at suitable

¹ See C. G. Trapnell and J. N. Clothier, *The Soils, Vegetation and Agricultural Systems of North Western Rhodesia: Report of the Ecological Survey, 1937.*

² See Chap. XI, pp. 608-11.

seasons and lives in temporary shelters. The building of huts and grain bins is closely associated with agricultural work, and the problems of improved village conditions are to a great extent connected with the stabilization and improvement of agriculture.

(b) Cattle-owning Tribes

Some cattle-owning tribes, such as the Masai, Nandi, and Turkana tribes in Kenya, and the Hima tribes of Uganda, pay little attention to cultivation; among others in East, West, and South Africa the care of herds is combined with cultivation. Among the latter, cultivation is left largely to the women, the men being absent at cattle posts or left free to protect the herds against wild beasts or to indulge in hunting. In tribal conditions, domestic animals, sheep and goats as well as cattle, are regarded as family possessions, measures of social importance, inherited within the family and given to other families as pledges for the good behaviour of women on marriage or for their proper treatment by the husband and his family. Breach of faith involves the return of these animals, and often of their increase. Live-stock are used as compensation for injuries. These customs give rise to complicated litigation and react against the sale of stock and consequently encourage overstocking.¹ Animals are killed for ceremonial reasons, but otherwise are rarely disposed of; their skins were formerly used as clothing, and the family cattle are named and in some tribes even share sleeping quarters with their guardians.

Even to-day no sort of segregation or culling of beasts is practised: the majority of stock remain in poor condition and are often in a state of semi-starvation and of little value for meat. The Native Economic Commission² considered that the purely economic conception of cattle held by Europeans is disruptive of the religious ideas of the Bantu, and that overstocking will continue as long as native cattle-holding rests on a religious rather than an economic basis. The Kenya Land Commission of 1933³ remarked that in the midst of plenty natives in pastoral and semi-pastoral areas are living under conditions of extreme poverty, and money

¹ See Chap. XVI, p. 1069.

² *Report*, U.G. 22, 1932, para. 34.

³ *Report*, Cmd. 4556, 1934, para. 1989.

for food and clothing is practically non-existent and will continue to be so until the products and increase of their herds are turned into some more useful and fluid kind of currency.

The system of herding at distant cattle posts or in the open has not encouraged the use of animal manure. Thus in Nigeria, where mixed farming is more developed than elsewhere, it is estimated that over two-thirds of the manure is wasted in the bush, and among East African and Rhodesian tribes the use of manure for fertilization is almost entirely ignored.

(c) *The Introduction of New Crops and Domestic Animals*

The African bush provides a variety of edible roots, indigenous fruits, wild honey, and the meat of wild game. It is still the custom to supplement diet with these. It is, for example, thought that the wild yams of the rain forests of West Africa formed the diet of the original tribes, but it seems that many of the foodstuffs and domestic animals¹ to-day in Africa have been introduced either by migrants from the north, by the Arab and Indian traders from the east, or by the Portuguese, and in modern times by the other European settlers. The sorghums and the bulrush millets and some other cereals are, however, indigenous to Africa; native oxen, except the Hamitic long-horn cattle and sheep, came from Asia. Bananas, rice, wheat, and sugar-cane were introduced by Arabs who settled on the East Coast in the seventh century and traded with India. The Portuguese, it is believed, enriched African agriculture with groundnuts, the sweet potato, cassava, and maize, introduced from their American colonies.² These early introductions were incorporated with the system of shifting cultivation, and the staple diet became a form of rough porridge made from one or other of the grains or from the cassava root, ground by hand between stones or pounded into a mortar, and supplemented by a relish of vegetables, meat, or milk. The simplicity of this diet has made the feeding of native labour easy and economical. Among a few tribes bananas form the usual food. The introduction of cassava and sweet potatoes by the Portuguese conferred an inestimable boon on many tribes by providing them with a famine crop which will flourish under conditions unfavourable to grain crops. In 1822 the

¹ See below, pp. 929-32.

² E. B. Worthington, *op. cit.*, chap. xii.

Portuguese introduced cacao from South America to San Thomé, and later, under European administration, coco-nuts and cloves came from America and the East, and also some cottons in the form grown for commercial purposes. On the other hand, all the cultivated species of coffee are indigenous.

(d) *The Recent Development of Native Agriculture*

In areas where crops have been introduced for sale and export, such as cotton in Uganda, or cacao on the West Coast, the peasant or garden farmer grows these on a small scale alongside his subsistence crop, or sometimes combines his own efforts with a system of *métayage*, allowing tenants to cultivate part of his holding and providing them with the means of cultivation in return for a share of profits. On the West Coast, where the present type of agriculture is a crude form of peasant or small grower's agriculture,¹ the system has resulted in new conceptions of land tenure² and in the virtual cessation of shifting cultivation. Cultivation of this kind is increasing, and stimulation of native production for export, resulting in intensive cultivation, increases the strain on the fertility of the land. Again there is evidence in the Gambia, for example, that concentration on the cultivation of export crops has resulted in deterioration in the cultivation of food crops and a dependence on the proceeds of farming for the purchase of foods, and there are instances in which the peasant or garden system of mixed cultivation has gradually changed to a plantation system, notably in the Gold Coast, where native cacao farmers have abandoned food-crop production and extended cacao production on a plantation scale.

In other areas European occupation and the consequent introduction of a money economy, with demands for taxation, has had two effects. First, many cultivators were induced to grow a surplus of native crops, and secondly, large numbers of the adult male population were removed for varying periods from their traditional routine of cultivation. The extension of this additional agricultural effort naturally took place to a greater extent in areas near to European enterprise, where money could often be earned

¹ G. H. Jones, *The Earth Goddess*, 1936, pp. 96-7.

² See Chap. XII, pp. 853 ff.

as easily from cultivation as by wage earning, and where conditions were made more difficult by the restriction of native lands.

As the methods of agriculture remain those of shifting cultivation, the available soil becomes rapidly exhausted. A system which often depends upon an area of two hundred acres or more of woodland for each family cannot endure indefinitely in areas where the population¹ is increasing and forests decreasing. In areas where the sale of native foodstuffs is not possible, but the male population goes out to work, the effect is no less disastrous. The balance of native agricultural life is upset and the duties of able-bodied men fall on those less able to bear them. For example, in areas where it was customary for the young men to climb trees and lop the branches, which were piled on garden patches and then burnt to enrich the soil, trees are now more easily cut near the roots and destroyed, and the deforestation and the erosion which to some extent always accompanied shifting cultivation are accentuated.² Again, long absence of the men from their families, and consequently the difficulty the women find in making satisfactory gardens without the assistance of their husbands,³ result in the break up of home life and in the migration of women to industrial areas, where they hope to be fed on rations with their husbands or other men. The spoliation of the land by bad methods of cultivation leads to further migration among men and discourages the return of those who become accustomed to wage earning and unwilling to return to the drudgery of unprofitable agricultural effort. Nor has the introduction of ploughs always resulted in improved methods; where crops are marketable the ambition of owners is to plough as much land as possible, and the indiscriminate exploitation of land by individuals, facilitated by a system of communal ownership which allows the cultivator to move from area to area, is characteristic of some native areas near the markets.⁴ The system of shifting cultivation is strained to produce a surplus, and, without regard for the future, large areas are put under millets or maize with no attempt to follow traditional methods of rotation or mixing of crops.

¹ J. M. Davis, *Modern Industry and the African*, 1933, p. 190.

² See Chap. XVI, p. 1088.

³ *Nyasaland Report on Emigrant Labour*, 1935, p. 35.

⁴ Northern Rhodesia, *Native Affairs, Annual Report*, 1936, p. 31.

In some areas, particularly in South Africa and in the High Commission Territories, it is clear that to an increasing extent natives now consume more food than they produce. The problems arising from this state of affairs will be discussed at length in a later chapter.¹

The effect of European occupation on the cattle-owning tribes has been no less far-reaching. More stable conditions and the application of veterinary science have resulted in a rapid increase in the live-stock population, particularly cattle. The rinderpest epidemic of 1895 provided a check, and the movements of tsetse fly have eliminated cattle in some areas; nevertheless, overstocking is now general and has led to widespread soil exhaustion and erosion.² The increase in stock is also due to the persistence of the customary ideas regarding live-stock already referred to. The problem of overstocking is discussed in another chapter in connexion with erosion.³

There is little evidence that the African cultivator is so conservative as to cling to methods which are obviously unwise or to resist the introduction of new crops.⁴ His own methods have been evolved and adapted to suit local conditions and his social habits have formed themselves around them. The conception of agriculture as a profitable industry is new to a people who are accustomed to look on it as primarily a struggle to wrest sufficient food from the soil to keep themselves and their families alive. But systems of shifting cultivation have not always resulted in plenty, and periods of hunger are frequent events in the life of native tribes. Instances of a change of methods of agriculture, apart from European influence, have not been unknown in the past; thus the staple food has in some areas been changed to cassava, where the cultivation of millet has become impossible owing to lack of woodland.⁵ The production of cacao in the Gold Coast and of groundnuts in Northern Nigeria are examples of the development of new industries almost without aid, when the African has been satisfied that production is possible and within his capacity. The wide adoption

¹ Chap. XX, pp. 1405 ff.

² For a discussion of veterinary control in relation to overstocking, see E. B. Worthington, *op. cit.*, chap. xiv.

⁴ O. T. Faulkner and J. R. Mackie, *op. cit.*, p. 6.

⁵ J. M. Davis, *op. cit.*, p. 191.

of maize and other crops, which are comparatively recent introductions, is further evidence of capacity of adaptation. While the scientific study of tropical agriculture is still in its infancy, it is clear that the European agriculturist, by careful study of native methods and social conditions, can do much to assist native agriculture in a period of transition, and can prevent the unwise extension of the growth of economic crops.

(e) *Game as a Food Supply*

In most territories the Africans have looked to wild animals as a sure supply of meat, and in areas where the presence of tsetse-fly precludes the keeping of cattle, game meat was and is still a necessary addition to diet.¹ European penetration has not only brought restrictions and difficulties in the way of game hunting, but has also resulted in some areas in a wholesale destruction of game; thus in one district in Northern Rhodesia, since the coming of the railway and the development of the mining areas, several hundred thousand head of game are said to have been destroyed by Europeans, and indiscriminate slaughter by hunters was frequent. The destruction of game in connexion with the control of tsetse-fly will be referred to in a later section.² African methods of hunting by game-drives did in fact result in wholesale slaughter, but they were carried out during certain seasons only; again, weapons for killing were primitive, and it is said that tribal warfare in the past denied access to considerable areas which virtually became game reserves. Experience has shown that earlier methods of hunting were not so wasteful to game life as the type of hunting which now takes place by natives armed with muzzle-loading or other guns. Prevention of the destruction of game and measures for its preservation are dealt with in all territories by legislation.³ It is sufficient here to mention that the problem of ensuring the perpetuation of a reasonable quantity of wild animals, which will provide a meat supply essential to the well-being of the indigenous population, is one which in the past appears to have received insufficient attention.¹

¹ *A Report on a Faunal Survey of Northern Rhodesia*, 1934, p. 82.

² See below, p. 933.

³ See E. B. Worthington, *op. cit.*, chap. vii.

II. AGRICULTURAL PRODUCTION BY NATIVES

In most native areas the staple native food crops are maize and millets, but in some, such as the highlands of Angola, the flour of the cassava root is an important diet; in others, as in Uganda, cooked plantains are a staple food and in parts of the West Coast yam flour, but on the whole the basis of native diet is a rough porridge made from one or the other of these two cereals. In the following pages some account is given of the extent to which the more important crops are cultivated and the degree to which they have been developed for sale and export; but it has to be remembered that millets and most root crops (and in some areas maize) are grown in small gardens by families and individuals for home consumption, and that the amount grown for cash sales is small and is in most cases the surplus of the food crop. Crops such as beans and peas are primarily grown for use as relish to be salted and eaten with the porridge; this in some areas is true also of groundnuts. Native gardens contain a variety of other subsidiary crops, such as pumpkins and cucumbers, and in the environs of villages wild spinach, tomatoes, peppers, and sugar-cane are usually found. Where maize is not the staple cereal, it is grown in the early rain season as an extra crop, usually for eating in the cob before it hardens; where maize is the favoured crop, millets, such as the fine bulrush variety, are grown in small patches.

Subsidiary crops are numerous and a survey in one limited and comparatively primitive area in Northern Rhodesia identified over one hundred varieties.¹ In a number of gardens examined in Southern Nigeria, where yams are the staple crop, it was found that in 93 per cent. corn was also grown, in 99 per cent. pumpkins, in 24·3 per cent. cassava roots, in 92 per cent. groundnuts, in over 80 per cent. some variety of beans, in 90 per cent. peppers, and many have other plants. In growing these subsidiary crops the woman cultivator has a peculiar interest; most are cultivated to provide the relish dishes into which the mush or porridge is dipped, and her success as a wife and housekeeper depends on her skill in

¹ *Report*, op. cit., Colonial 145, 1938, pp. 217 ff. See also C. G. Trapnell and J. N. Clothier, op. cit., pp. 26-30.

varying diet from her gardens.¹ There is a variety of edible wild plants, roots, mushrooms, and fruits, and a familiar sight of the African bush is that of parties of women collecting these during the appropriate seasons. The sweet potato grows freely over a wide range of tropical country; it is easily propagated by vine cuttings and has a long period of growth. It is important as a standby in times of scarcity of other foods, and its trailing habit and dense foliage serve to prevent erosion; it forms a relish, like spinach, and also a supplementary cattle feed. The cultivation of European potatoes is unimportant except in Kenya, where they are grown for sale to Europeans, and in the eastern parts of the Belgian Congo, where they are said to be gaining favour as a native diet; the sweet potato is more nourishing and it would be unfortunate if it should be replaced.

Wheat is grown by Africans in the Union and in the Transkeian territories, where the General Council has provided threshers; in Basutoland 124,970 acres were estimated to be planted in 1936. In French West Africa and in the Costermanville Province of the Belgian Congo some wheat is grown, but generally speaking it is not consumed by Africans and is grown only under European encouragement for marketing. Rice, although not generally a staple diet, is important in this respect in some areas and of growing importance as a cash crop; the extent of its growth will be described later. It is necessary to describe at length the more important native food crops such as cassava, yams, ground-nuts, sesame, beans and peas, and bananas, which are assuming greater importance as cash or export crops, and to give some account of the major commercial crops grown by Africans: cotton, cacao, coffee, palm oil and kernels, tobacco and fruits.

Other minor crops, though of less general importance, are of interest and are possibly capable of further development. Thus Sierra Leone is the principal source in the British Empire of piassava fibre, obtained from the wild raphia palm, and in 1936 exported 3,558 tons. Improvement in the quality of the bark marketed has been effected by means of a system of inspection introduced under the Native Produce Ordinance.² A small

¹ See C. D. Forde, 'Land and Labour in a Cross River Village', *Geographical Journal*, vol. xc, no. 1, 1937.

² No. 16 of 1928.

amount, 455 tons, was exported in the same year from Nigeria. Native cultivation in the Central Province of Nigeria was about 100,000 acres in 1935. Cultivation is successful only at the higher altitudes, and the tree improves soil fertility and checks erosion when planted on eroded land and steep hill-sides.

Jute is an important product of the Bas-Congo, a district of the Belgian Congo; in 1936 the Maniango district produced 1,223 metric tons.

Wattle is grown in Kenya, where it was established after its successful cultivation in South Africa. Ginger thrives in West Africa. It is planted on patches of rich soil, often near villages where it can conveniently be manured; it is not of high quality but has been improved recently. In Nigeria exports have risen from 15 tons in 1930-1 to 342 tons in 1936-7. In Sierra Leone, where the quality has been improved by instruction in drying and by inspection, the crops yielded 1,642 tons in 1936. Kola nuts are chewed in West Africa by natives on account of their stimulating and sustaining properties. In former years Nigeria imported kola nuts from the Gold Coast and Sierra Leone; now internal production has increased until there is an export surplus. Cultivation has been recommended, to replace cacao in districts where the economic life of the cacao-tree has been found to be too short, and seed and plants of the better varieties have been distributed. In 1936 the Gold Coast exported 430 tons of nuts and Sierra Leone exported 2,301 tons to other West African territories: the trade in these territories has been affected by higher import duties in French West Africa and the increased production in Nigeria. French West Africa exported 55 metric tons of kola nuts in 1936.

The commercial uses of the shea nut, collected from the wild plant, have been developed in French West Africa; in the first nine months of 1937, 4,500 metric tons of nuts and butter were exported. In French Togoland a small amount of nuts was collected for export in the northern division.

Wild rubber is found in many areas, including certain of the French territories, but the export is inconsiderable. Native cultivation of rubber has been introduced in the Coquilhatville Province of the Belgian Congo.¹

¹ See below, p. 919, and E. B. Worthington, *op. cit.*, chaps. i and xii.

An important minor industry to which more attention has been given recently, for example in Northern Rhodesia, Tanganyika, and Sierra Leone, is the production of beeswax. Thus, in Tanganyika, where instruction is provided in the preparation of wax, 524 tons were exported in 1936, and in Northern Rhodesia in one district natives earn tax money by sales which are assisted by government. In Sierra Leone wax of high quality is being produced; exports from that territory rose from 15 cwt. in 1934 to 58 cwt. in 1936. Three hundred and one metric tons of beeswax were exported from French West Africa in the first nine months of 1937. Wax has a certain commercial importance in the Ubangi region of Equatorial Africa. In the Belgian Congo, efforts are being made to develop a wax industry, and exports in 1936 amounted to 115 metric tons. The collection of honey and wax is, however, sometimes accompanied by extensive burning.

As will be seen, efforts are being made to encourage the cultivation of fruit trees; in a countryside in which wild fruit abounds little interest is taken in trees of the type which need continual care. In Central Africa paw-paws and melons are grown, but the system of shifting cultivation, involving the frequent removal of villages, discourages fruit-tree planting.

In the following survey of main crops no attempt is made to differentiate between cash and food crops, and, as may be expected in the case of crops grown in mixed gardens by innumerable individuals, it is not always possible to give an approximately accurate estimate of the amount of each crop grown annually in each territory.¹

(a) *Maize*

The successful growth of maize requires fertile soil. In the Union of South Africa and in the High Commission Territories, however, where maize porridge is the main diet of the native people, it is grown continuously on the same land in all native areas whether the soil is suitable or not, usually without any attempt at rotation with a legume or root crop, and, as may be expected, the return is low and production is frequently insufficient to meet food requirements.²

¹ Much of the factual material which follows was collected by Mr. A. J. Findlay, C.M.G.

² Union of South Africa: *Report of the Department of Native Affairs, 1935-6*, U.G. 41, 1937, p. 38.

In these conditions the average output would seem to be roughly $2\frac{1}{2}$ to 3 bags an acre, as against the 6 or 7 which similar land might yield under improved methods of cultivation. In Southern Rhodesia about 400,000 acres of maize are cultivated, by natives for home consumption. The yield was estimated at over 1,000,000 bags¹ in 1936, of which about one-quarter were sold or bartered. In Northern Rhodesia maize is cultivated extensively by the cattle-owning people in the Barotse Province, on the Kafue river flats, in the Luangwa valley, and in the Fort Jameson area;² elsewhere it is usually a subsidiary crop, grown in fertile patches on plains and near rivers. Near the railway line ploughs are used³ and a considerable surplus is grown for sale; in 1936 150,000 bags were thus disposed of. In Nyasaland maize is a staple food crop; in Tanganyika maize is only second in importance to millets, and some 800,000 acres are estimated to be under cultivation, almost entirely for home consumption. In Kenya the estimated area under maize in the native reserves is 1,750,000 acres; it is one of the most important food crops and there is a surplus available for sale. In Kenya maize grows readily at all altitudes from the coast upwards, provided that the rainfall is sufficient, and in the highlands yields on an average 1,400 to 1,600 lb. per acre; but the distance from markets, and the high cost of both rail and ocean freights, discourage its growth as an export crop. Efforts are being made to improve the type grown by Africans, and the introduction of the early maturing Muratha seed, which is apparently resistant to white blight and fusarium diseases, is said to have doubled the yields of native maize in the Central Province; South African seed is also under trial. In Uganda maize is grown as a subsidiary food crop; it is planted among other crops and the cobs are picked and cooked before they are ripe. In the coastal regions of Nigeria and the Gold Coast maize is an important food crop, but, owing to the extensive growth of more profitable crops for sale, it has little importance as a crop for sale or export. On the West Coast attempts to introduce new varieties have generally failed, as the native variety can be successfully grown and is considered more palatable.

¹ Bags are usually 200 lb. in weight.

² *Report*, op. cit., Colonial 145, 1938, p. 225.

³ See above, p. 885.

In French West Africa maize is an important food crop, especially in Dahomey. An average of 450,000 metric tons of maize is estimated to be produced annually from a cultivated area of about 4,000 square kilometres. French Togoland exported 7,807 metric tons in 1936, principally from the southern areas. In the French Cameroons maize is grown in the south-west; 4,189 metric tons were exported in 1936.

In the Belgian Congo maize is a staple food. Cultivation has been extended under the 'educative' system,¹ primarily with a view to increasing the food supply. The areas required to be cultivated were increased from 85,000 hectares in 1935 to 135,000 hectares in 1936. Whereas in 1927 it was necessary to import over 10,000 metric tons of maize for consumption at the industrial centres, there was a small export in 1933, which rose to 4,214 metric tons in 1936. It is also grown as a food crop in the mandated territory of Ruanda-Urundi.

(b) *Millet*s

Millet is grown largely where conditions are unsuitable for maize, and millet flour provides a staple food for large sections of the native populations in South Africa, the Rhodesias, in the East African territories, and in the interior of West Africa. Production is almost entirely in the hands of natives. The great millet or sorghum, also known as Kaffir or Guinea corn, is the most important millet crop, but in drier areas the lesser millets, such as pennisetum, the bulrush millet, and eleusine or finger millet, are widely grown, both as pure or mixed crops. Sorghum is an important crop in the Union and the High Commission Territories, Basutoland alone producing nearly 26,000 tons; Nyasaland and Northern Rhodesia also depend very largely on millets for food. In Tanganyika they are the staple crops for food and for the brewing of beer, and are widely cultivated; it is estimated that two million acres are under cultivation and produce annually about half a million tons. Sorghum is grown extensively for food in Kenya, and in the drier parts of Uganda the finger millet is the staple cereal food crop; it is estimated that over a million acres are so planted. In Northern

¹ See Chap. XI, pp. 633-5.

Nigeria the principal grain crops are bulrush millet, or gero, and sorghum. Gero is quick-growing and requires little pre-cultivation; hence it is the first crop to be planted in fields where other crops are also grown. It is also resistant to drought and adaptable to different soils. The demand for sorghum is such that it becomes a money crop to cultivators who are favourably situated for markets. Every part of the plant is used: the flour for human food, the bran for feeding stock, the leaves for fodder, and the stalks for building houses and fences.

In French West Africa millets are the staple food throughout the northern areas, and also in the palm belt in Dahomey. An average of 30,000 square kilometres is estimated to be planted annually, giving a yield of 2,000,000 metric tons. In Togoland under French mandate, the estimated annual production is 20,000 metric tons. In the Cameroons under French mandate, millet is the staple food of the northern populations; in 1936 a single region (Logone) produced 150,000 metric tons, of which one-third was exported to Nigeria and French Equatorial Africa. Millets are important as a native food crop in Ruanda-Urundi and in some parts of the Belgian Congo.

(c) *Rice*

Native rice is grown as a subsidiary food crop in a few areas in Nyasaland and Northern Rhodesia, and also in other parts of East Africa. In Tanganyika 150,000 acres are said to be under cultivation and leave a surplus for export which in 1936 amounted to 6,513 tons and went to Kenya and Uganda. In Kenya the cultivation of rice is increasing in Nyanza and the coast provinces. Two thousand bags were exported in 1936 from the Nyanza area where, prior to 1934, no rice was grown. In Uganda 2,045 acres were stated to be under cultivation in 1936. In East Africa rice for the native people remains a luxury rather than a foodstuff. Most of the hill and dry-land rices of West Africa are derived from the indigenous African species and have a grain with a red skin which is said to make them unsuitable for export. In some areas it is a staple food, particularly in Sierra Leone, where it is estimated that 175,000 tons a year are grown, and imports have been reduced from about 2,000 tons annually to practically nil. An internal market is created by the mining industry, which consumes over 4,000 tons annually.

In Nigeria, swamp rice is grown in the river valleys where conditions are suitable. By controlling the flood water, puddling the land, and transplanting seedlings from a nursery bed instead of broadcasting the seed, the department of agriculture has obtained yields of 2 tons of paddy per acre of white exotic rice in experiments; experiments in rice-growing in mangrove swamps have also given encouraging results. In the Gold Coast, the attempt to encourage rice-growing has not met with success, and imports continue to increase, the 1936 figure being 233,666 cwts. The uniformly white type of imported rice is preferred to the coloured native varieties, and a government mill is unable to obtain sufficient quantities of local paddy for full working capacity.

In French West Africa the average area annually planted with rice throughout the whole federation is 4,000 square kilometres, and the yield is estimated to be about 400,000 metric tons. It is the principal crop grown in the irrigated area at Baguinéda in the Niger delta,¹ which is expected to carry 5,000 hectares. The marsh rice, 'dici', has recently been introduced from India for planting in the swamp areas, and 'fossa' for inland cultivation. At Kokry, in the Sansanding irrigated area, about 8,000 hectares of rice are expected to be planted. The population of Senegal, which at present imports 50,000 metric tons of rice, is regarded as the most hopeful market. At the Diré Company's concession near Goundam, where each native cultivator is required to plant one hectare of millet and one of rice as food crops, the yield of rice is 2,400 kilos per hectare. Rice is a traditional native food crop in the Casamance valley of Senegal and in Guinea, where it is grown together with maize in regions liable to seasonal flooding. Cultivation for export has recently been stimulated in Guinea.

In the Belgian Congo 4,933 metric tons of rice were imported in 1927; local cultivation for sale to the industrial centres has since been encouraged, particularly in agricultural areas close to these centres, and in 1936 1,173 metric tons were exported.

(d) *Cassava (Manioc)*

Cassava is a staple food in many of the tropical and sub-tropical areas of Africa and its cultivation is widely encouraged as a

¹ See Chap. XV, pp. 1050 ff.

food reserve crop in case of scarcity. It is not universally popular and some tribes are ignorant of the methods of preparing the root, or dislike cassava as a food; the starchy porridge made from the cassava flour is said to be more filling than nourishing. There are two distinct varieties, the bitter and the sweet; the root of the bitter variety contains cyanogenetic glucoside which develops hydrocyanic acid;¹ in the sweet variety the glucoside is confined to the skin. Thus, the roots of the sweet variety, when skinned, can be eaten raw, while the bitter variety has to be soaked in water or cooked to dissipate the poison. Cassava is comparatively free from pests and diseases but is subject to a virus disease known as mosaic, which has increased in recent years.

In West Africa cassava, which is grown commonly in the rain forest area, is generally planted on ridges as the final crop before the farm is abandoned, and left to fend for itself. It is also grown on land in the vicinity of large towns where no other crop will grow. It was considered at one time to be an exhausting crop, but experiments in Nigeria have proved that it is not so, if the stems and leaves are not removed from the land.

In French West Africa, where it is grown particularly in Dahomey, the average annual crop is one million tons from a cultivated area of 4,000 square kilometres. In the mandated area of Togoland an export of tapioca made from the cassava root began in 1932 with the small quantity of 6 metric tons; 1,083 metric tons were exported in 1935, but the figure fell to 466 on account of drought in 1936. In the Cameroons cassava is grown as a food-stuff in the forest and savannah zone, and the Doumé subdivision in 1936 produced a surplus for sale to mines at Bétaré-Oya. In the northern areas the cultivation of manioc is encouraged as a precaution against famine due to locust invasions.

In Ruanda-Urundi certain regions have been found unsuitable for cassava, but cultivation is being extended elsewhere. Over 5,000 cuttings of varieties resistant to mosaic disease were distributed in 1936.

(e) *Yams*

The term 'yam' is sometimes used to include all the tropical tubers, but strictly speaking it should be applied only to varieties

¹ See E. B. Worthington, *op. cit.*, chap. xii.

of *Dioscorea*, the big yam, which is cultivated in tropical Africa, principally in the coastal regions and middle belt of West Africa, where it is a staple food crop. In most parts of East Africa the rainfall is inadequate for yam cultivation. In typical yam-growing areas only good land is used and cultivation is carried out carefully, a usual practice being to plant on mounds of soil or in well-made ridges; in some cases the mounds are about 4 or 5 feet high and correspondingly broad. Under good cultivation huge tubers weighing 50 to 60 lb. can be produced. In all yam fields other crops are interplanted on the sides of the hills or ridges, and it is seldom that two crops of yams are taken off the same land in succession. Yams are exported from French Togoland; in 1936 the amount exported was 258 metric tons.

Coco-yams (*colocasia antiquorum*) are widely cultivated in the wetter areas of tropical Africa, but are usually regarded as being of secondary importance, and do not occupy any specific place in systems of cultivation, being often planted in odd pieces of land and under the shade of trees where few other crops will thrive. Their tolerance of shade allows them to be grown as a catch crop and ground cover under permanent crops, but in the forest areas of south-eastern Nigeria and the British Cameroons they are an important food crop. They are not related to the *Dioscorea* yams, and it has recently been found that the bulb contains toxic substances.

(f) *Groundnuts*

Groundnuts can be grown as an annual crop on light soils in almost any tropical or sub-tropical country, and cultivation in Africa extends from the Gambia all along the West Coast across Central to East Africa and down to the Union. The groundnut is valued as a foodstuff, and its oil for domestic purposes; and it is said that more extended use would remedy deficiencies in native diets. The plant acts as a soil renovator, and the haulms are a valuable addition to the fodder supply in mixed farming. In Kenya, Nyasaland, and Northern Rhodesia all production is absorbed by local requirements. In Northern Rhodesia, for example, the local demand at the mines has to be supplied by imports from outside the territory.

In Tanganyika the amount exported varies widely with season and price. It is estimated that in 1936 there were 290,000 acres under groundnuts. In Uganda cultivation is estimated at 167,124 acres, but exports were only 1,465 tons in 1936. Marketing arrangements are in the hands of a single firm licensed under the Native Produce Marketing Ordinance¹ for three years. Experiments on inter-planting with cotton have given good results and show a possible way of increasing production without diminishing the cotton acreage. Export production in Nigeria is almost entirely confined to the drier areas of the Northern Provinces, especially in Kano Emirate. In 1936, 218,389 tons were exported, or 18 per cent. of the total exports: only uncorticated groundnuts are exported from the interior. Production costs in this crop have to be kept low, as high transport charges have to be met, owing to the great distance from the port. In the Gambia the export of groundnuts amounted in 1936 to 49,654 tons, or over 95 per cent. of total exports. The industry is over a hundred years old, for there is a record of an export valued at £838 in 1836: here again only uncorticated nuts are exported. French West Africa is the leading exporter of groundnuts in Africa, the total exported in the first nine months of 1937 having been 395,000 metric tons of uncorticated, and 123,000 metric tons of corticated nuts. Senegal is the principal source, and the impoverishment of soil in the Rufisque district through over-production has led to experimentation with manures in the central belt, which is now the main producing area. In the extreme north the control of flood-waters and the construction of irrigation canals are also under consideration.² In Togoland the communal cultivation of groundnuts was first organized in 1935 through the medium of the *sociétés de prévoyance*.³ In the Mango subdivision in the extreme north this represented the first introduction of the population to a money economy, and rivers are being specially bridged to allow for the transport of the crop. The exports in 1935 amounted to 1,394 metric tons, mainly from the northern areas; in 1936 a large proportion of the crop was lost through drought.

Groundnuts are also exported from French Equatorial Africa,

¹ Ordinance 20 of 1932.

² See E. B. Worthington, *op. cit.*, chap. xii.

³ See Chap. XXI, pp. 1477 ff.

but high transport charges make cultivation unprofitable in the interior; in the French Cameroons cultivation is encouraged only in regions unsuitable for oil palms: an excellent quality is obtained from the northern area, and in 1936, 12,294 metric tons were exported.

Exports from the Belgian Congo began to be important in 1934, and attained 6,368 metric tons in 1936. This crop is, however, held to be primarily valuable as an addition to native diet, and cultivation is encouraged largely for this reason; the area required to be planted was increased from 37,600 hectares in 1935 to 102,000 hectares in 1936. Groundnuts are also sold to the mining areas. In Coquilhatville Province the crop is grown in rotation with cotton. It was introduced in the mandated area by means of free distribution of seed in 1935; cultivation is spreading, but only for food.

(g) *Sesame (simsim)*

Sesame (*Sesamum orientale*), also known as simsim and benniseed, is grown in both East and West Africa: it grows freely in areas where the rainfall is moderate. The seed contains oil which can be used as a substitute for olive oil, and is used in native food; it is much used as a relish. In East Africa oil is produced in Indian-owned crushing mills often operated by camel power. In Tanganyika, where in some areas this is the staple crop, steps are taken to ensure supplies of pure white seed, which commands a premium over coloured kinds. In Kenya the Nyanza Province is the main source of supply, and cultivation is being encouraged in the Coast Province, where introduced white-seeded varieties are under trial. In 1936, 3,958 tons of seed and 85,455 gallons of oil were exported from Kenya. In Uganda this crop is of greatest importance in the Northern Province, where it is grown for sale when prices are favourable. In Nigeria the establishment of an agricultural station in the Benue Province in 1924 gave an opportunity for combined efforts of trading firms and the Department of Agriculture to encourage and extend the cultivation of benniseed, which is the money crop of the Munshi farmers:¹ as this area has no other cash crops, cultivation is likely to be extended in spite of

¹ O. T. Faulkner and J. R. Mackie, *op. cit.*, pp. 127 ff.

low prices. Nigerian exports have risen from less than 2,000 tons in 1924 to 13,186 tons in 1936, and quality has been raised by the distribution of pure seed. Production in the Northern Territories of the Gold Coast is for local consumption. Sierra Leone exported 409 tons in 1936. French West Africa in 1936 exported 868 metric tons of sesame; in the French Cameroons it is cultivated in the savannah region, where no other oleaginous plants will grow, and white-seeded varieties are being introduced; exports in 1936 were 1,079 metric tons.

(h) *Pulses*

Pulses such as beans and peas include a very large class of leguminous crops that are widely cultivated for food purposes with occasional small surpluses for export. The favourite cowpea (*Vigna unguiculata*) is to be found growing in most native gardens in tropical Africa, and the tall pigeon pea (*Cajanus Cajan*) is common. In the Union of South Africa beans are increasingly grown as a subsistence crop in the high veld districts and the coastal areas of Natal and the Ciskei, and their introduction has been recommended in Bechuanaland for late planting.¹ In Swaziland the principal legume grown for food is the nhlubu bean.² Throughout East Africa beans and peas of all sorts are consumed locally. In Kenya imported varieties of beans are grown in the highlands, and tepary beans do well in the coastal area; the export of beans was nearly doubled in 1935, largely owing to the new system of inspection, whereby samples containing over 75 per cent. of one variety were picked over until they were pure. A valuable export trade with South Africa has been established with the Rose Coco and Canadian Wonder varieties, and in some districts beans are found to be a more profitable crop than maize for native cultivation.

In West Africa the phaseolus bean is said to have been cultivated for over a thousand years, and recently a variety has been produced that may fulfil successfully the dual purpose of a green manure and a food. Various pulses are grown throughout the French

¹ *Report on the Financial and Economic Position of the Bechuanaland Protectorate*, Cmd. 4368, 1933, p. 139.

² *Report on the Financial and Economic Situation of Swaziland*, Cmd. 4114, 1932, p. 145.

colonies, and French Togoland in 1936 exported 34 metric tons of haricot.

The soya bean, which would form a valuable addition to native diets, has been tried in South and Central Africa with doubtful success, as conditions do not appear to be suitable. It appears, however, that some areas in the East African highlands and in Nyasaland are suitable for a special variety bred with regard to local conditions.

(i) *Bananas and Plantains*

Bananas and plantains are cultivated very extensively in Africa where climatic conditions are suitable; they thrive best in areas of high rainfall, but will grow where the rainfall is as low as 20 to 30 inches. In this discussion the term 'banana' is applied to the sweet fruit, and plantain to the variety which requires cooking. For native consumption the plantain is the more widely cultivated, and in some parts constitutes the staple food crop; thus in Uganda over a million acres are under this crop. In Tanganyika the estimated area under plantains and bananas is a quarter of a million acres. Farther south conditions generally are said to be too dry for successful cultivation, although there is a considerable production of bananas of indifferent size and quality in the coastal belt of Natal. In the southern portions of the Gold Coast, Nigeria, and particularly the Cameroons, there is a big consumption of plantains, often as supplementary to yams.

Bananas and plantains for native consumption are frequently planted in and around villages, where household refuse serves as manure, and are sometimes interplanted with permanent crops and used for shade purposes with coffee and young cacao. The stools are allowed to multiply almost indefinitely, and the result is often a veritable forest of plants. In some areas a flour useful for native bread-making is prepared from dried plantains, and liquor is extensively brewed and distilled from plantains and bananas, but there is no commercial preparation of banana fibre in Africa.

Before 1914 the German administration had organized an export trade in fresh bananas from the Cameroons, but it was not until after the War that other West Coast countries considered the possibilities of such a trade. Some of the big fruit companies

operating in the West Indies and South America explored the West Coast, but found that conditions in the British areas were not suitable for production on the large scale which they desired. In 1933 the Gold Coast Government arranged some trial shipments. The results were encouraging, and after an unprofitable period shipments are now said to show some profit, but poor soil and lack of attention are responsible for a high proportion of small bunches, and it is held that the export trade is unlikely to be successful unless larger bunches can be produced.¹ A survey of soil conditions has been made by the Agricultural Department, and farmers are advised of suitable areas.

There has been greater success in organizing the export trade from French territories. French West Africa in the first nine months of 1937 exported 35,000 metric tons of bananas. Commercial cultivation of bananas was introduced into the French Cameroons in the coastal region in 1932, largely on estates originally held by Germans; it has been extensively developed both by natives and Europeans, principally in the neighbourhood of the railway. There is now a regular steamer service for the export of the fruit, and the exports for 1936 were 16,865 metric tons. There is a large export of bananas from the Cameroons under British mandate.

(j) *Cotton*

Indigenous African cottons exist, but the cotton of commerce has been derived from American long-stapled varieties introduced at various times since the beginning of the twentieth century. The climatic conditions required by cotton are moderate rainfall during the growing period, and dry weather for the setting and ripening of the bolls; if the rains last too long or stop too early, crop yields are seriously affected. Cotton is grown in some areas as a mixed crop and often planted in the same gardens as the staple food crops; its development as a native crop is due to the ease with which cultivation can be combined with that of subsistence crops. It is believed to have possibilities as a native crop in portions of Natal and the inland districts of Zululand, but development depends on

¹ F. A. Stockdale, *Report on his Visit to Nigeria, Gold Coast and Sierra Leone, 1935-6*, C.A.C. 270, 1936, pp. 69-72.

further research; it is thought possible that some form of collective production might be introduced.¹

It was decided in 1935 to stimulate the cultivation of cotton by natives in Southern Rhodesia, and in 1936 it was introduced as one of the four-crop rotations in school demonstration plots. The Cotton Research and Industrial Board distributed seed and has agreed to buy the crop. Experiments with cotton as a native crop have been under trial in Northern Rhodesia since 1932: an output of some 4,000 bales is regarded as possible. In Nyasaland the original introduction was Egyptian seed, later replaced by American Upland; the type now grown is derived from the American strain, U₄, introduced from South Africa. It is estimated that there are 82,000 acres under native cultivation, which produced for export 13,301 bales and 1,629 tons of cotton seed in 1936. Following on a visit of Professor Munro to advise on insect pest control, much caution is advised in the extension of cotton growing in Nyasaland until more is known about cotton pests, particularly red bollworm.

In Tanganyika exports of cotton grown by native peasant farmers show a remarkable increase from 13,587 bales in 1931 to 63,130 in 1936, and increases are expected to continue, but yields of seed per acre are considerably lower than in Uganda. Tanganyika depends on cotton strains from Uganda and Nyasaland.

In Kenya cotton is entirely a native crop: it has been exported in small quantities for many years, but not until 1930 was there a definite increase in cultivation followed by a steady expansion. Thus in 1930-1, 783 bales of 400 lb. each were produced, and in 1935-6, 16,165 bales. Cotton is now the chief cash crop in the native reserves in the Nyanza Province and the coastal belt. It is being tried in the lower-lying parts of the Central Province, but generally cultivation is restricted to levels below 4,500 feet. Twelve ginneries were in operation in 1936. In the Nyanza cotton area strains from Uganda have been successfully introduced. In some areas cotton has been satisfactorily worked in with food crops, but in others it is causing over-cropping, and where it is grown on hill slopes it is said to be responsible for soil erosion.²

¹ Union of South Africa, *Report of the Department of Native Affairs, 1935-6*, U.G. 41, 1937, p. 39.

² See Chap. XVI, p. 1100.

The remarkable development of the cotton industry in Uganda in recent years has been made possible by the extension of the railway and by the development of roads. The first recorded export of a few hundred pounds of lint was in 1902, and it was not until 1906 that an appreciable export of 500 bales was made; from that time development was rapid, reaching 20,000 bales in 1911 and 316,000 in 1935-6. There appears to be no evidence of indigenous cotton in Uganda; the existing native cotton was introduced by Arabs. Sir Samuel Baker introduced Gallini cotton in 1872, but there is no trace of further introductions until 1903, when Egyptian and American Upland varieties were introduced for trial. Egyptian cotton did not do well and it was decided in 1907 to restrict importation to American varieties. Between 1903 and 1910 Buganda was the principal producing area with about 22,000 acres. Between 1911 and 1920 standard varieties were adopted and the industry was developed on the basis of the American Upland varieties Allen and Sunflower, the latter being generally adopted before the end of the period. From 1921 onwards local selected varieties were adopted for general cultivation, beginning with selections from Nyasaland Upland, which had been introduced for trial in 1915. These were line selections from a mixed crop of long staple Upland, with Florodora predominating. Subsequently various introductions were tried and discarded, and in 1929-30 came the varieties U₄ and U_{4/4/2} bred by the Empire Cotton Growing Corporation at Barberton in South Africa; the latter is the parent of many selections now being cultivated. Cotton is grown mostly in the Eastern, Buganda, and Northern Provinces, where there is a rainfall of about 50 inches. In the Eastern Province the extension of cultivation has led to the widespread adoption of ploughing, to an extent which is producing exhaustion of the soil.¹ In the Buganda Province yields have been falling off, and it is suspected that this may be due to soil erosion resulting from cultivation on steep slopes, since experiments in America have shown that cotton grown on eroded soil is inferior. The first power gin was established at Kampala in 1906, and by 1914 there were 20 ginneries working. There are now 194 ginneries, of which 59 do not operate, but serve as buying centres. The pro-

¹ See Chap. XVI, pp. 1099-101.

ceeds of the export tax, imposed in 1919, were at first devoted to the development of the industry, but now go to the general revenue. The principal markets are in Bombay and Japan. Uganda cotton enjoys a premium over American middlings, but this may be lost if the standard is allowed to deteriorate through the mixing of strains. Both here and in Tanganyika efforts have been made to find local markets for cotton-seed oil, so that seed, which is at present destroyed when prices are low, may be used as a fertilizer. It has been suggested that cotton-seed oil may be used as fuel for Diesel engines, and the appointment of a chemist to undertake research on the subject was recommended by the Uganda advisory committee for the development of native agricultural production.¹

In Nigeria cotton has been grown from time immemorial to supply the demands of the native hand-spinning and weaving industry, but the great bulk of the export production comes from the Zaria and Sokoto Provinces in the north, where American cotton, Allen's Long Staple, has practically replaced the native variety. In the Southern Provinces an improved native type known as Ishan is used. In 1925-6, when the price paid for seed cotton was 2½d. per lb., the production was 37,356 bales, but this level was not reached again till 1934. In 1935-6 about 50,000 bales were purchased at 1½d. per lb. The average yield in Zaria is said to be 150-180 lb. an acre, but on well-manured land 450 lb. has been reached. It is interesting to note that prices in the local markets throughout Nigeria for cotton for spinning and weaving are often above export prices.

In French West Africa cotton is one of the principal crops grown on the irrigated lands in the Niger basin;² the *Association Cotonnière Coloniale* supplies selected seed and sometimes buys the crop as agent for the government at a guaranteed price of 0.90 frs. a kilo, with a bonus when the market price is high enough. The cotton supplied is 'improved Allen' from Nigeria, which is also used in the northern regions of Dahomey; experiments are also being made with Peruvian types. Native cotton is sold in the open market: it is of short staple and gives a percentage of about 25 in ginning.

¹ *Report of the Sub-Committee on Utilization of Cotton-seed, 1936.*

² See Chap. XV, p. 1050.

The Diré Concession was originally granted for cotton in 1919, but serious development began only in 1930.

Four cotton-buying companies operate in French Equatorial Africa, where production, largely stimulated as an 'educative' process, attained 16,600 metric tons in 1934-5. It was announced in 1935 that the maximum area had been brought under cultivation and attention would be directed to increasing yields. A type of American Upland is used and the crop is grown mainly in the Ubangi-Shari region, where soil and climate are most suitable. It is exported by the Niger route, which is open only for two or three months in every year.

In French Togoland cotton is grown in association with yams in the central plateau area; in 1936, 1,515 metric tons were produced. It is regarded, with groundnuts, as the most hopeful cash crop in the north of the Cameroons, but has only recently been introduced: in 1936, 69 metric tons were exported.

In the Belgian Congo cotton was the first crop to be introduced by the method of 'educative' cultivation imposed in 1917.¹ The Administration fixes the purchase price. The principal company, the *Compagnie Cotonnière Congolaise*, founded in 1920, undertakes ginning and marketing. By 1936 there were 125 ginneries in the Congo. The extension of cotton cultivation is still being actively pursued. The chief producing areas are in the valleys of the rivers Uélé and Ubangi in the extreme north, and Sankuru and Kasai in the south. The highest average yield in 1936 was given as 410 kilos per hectare in some parts of Tshofa Territory in the Lusambo Province. Total production for that year was 89,574 metric tons from a cultivated area of 304,302 hectares; of this 26,485 metric tons was exported. In the mandated area cotton is grown in the Ruzizi plains and around Usumbura, and in 1936, 11,000 native planters cultivated about 3,300 hectares. The average yield was said to be 608 kilos per hectare, and the total production 2,010 metric tons.

(k) Cacao

The cacao tree, *Theobroma cacao*, a native of the tropical forests of Central and South America, requires a high temperature and

¹ See Chap. IX, p. 634.

a humid atmosphere, and flourishes under West African conditions. It was first brought from America to San Thomé by the Portuguese, and afterwards established on the mainland, first on the Gold Coast and later in Nigeria; Sierra Leone produces a negligible amount, but French West Africa (the Ivory Coast) is exporting an increasing quantity. Cacao is native grown, except in the Cameroons, where large plantations, some of which continue to be exploited by European owners, were established under the German administration. It does not thrive in East Africa, which is too dry, but attempts have been made to establish it in Tanganyika and a few tons are exported from one plantation.

The cacao industry in Nigeria has not been developed to the same extent as in the Gold Coast, although production rose from 33,934 tons in the 1926-7 season to 70,000 tons in 1936-7, as conditions are only suitable in areas in the west of the territory. In the palm belt the soil conditions are unfavourable and the trees quickly deteriorate and die back before they are 18 years of age. The original exports, which were almost entirely unfermented and often badly dried, were said to be the poorest quality on the world market, but considerable improvement was made through the organization, by the Department of Agriculture in 1922, of fermentation centres on which the introduction of the co-operative movement to Nigeria was based.¹ In the mandated area of the Cameroons native production is mainly in the Kumba District, where there is a large co-operative marketing union,² and in 1936 it amounted to two-thirds of the total output.

The Gold Coast cacao crop for the seasonal year 1935-6 constituted a record at 285,351 tons. This large crop, which supplies nearly half of the world's demands, is produced from the forest belt, where its cultivation occupies about 950,000 acres, and the development of the industry has been so rapid and successful that it has over-shadowed other agricultural activities, and caused a disproportionate concentration on a product confined to a limited area, and employing only a small proportion of the total population. In the Gold Coast cultivation is almost exclusively in the hands of peasant farmers, and it is estimated that there must be over a quarter of a million cacao farms varying in size from about

¹ See Chap. XXI, p. 1474.

² *Ibid.*, p. 1475.

2½ to 6½ acres. As in other areas, the source of labour is usually the owner's family, but labourers, generally from the Northern Territories, are employed on the larger farms. As little attention is paid to cultivation, and pruning is neglected, and no attempts at drainage are made, production costs are kept at a low level and producers have been able to compete successfully in the world market.

The type of plant cultivated, the yellow podded Amelonado, is uniform and yields well over 500 to 600 lb. of dried cacao per acre. The crop is harvested at two seasons, the main season from August to January, and the mid-season in May and June. The ultimate quality of the crop depends almost entirely on the care which is exercised during the fermentation, although drying, which is done in the sun, is also important. The standard Gold Coast product is not a cacao of high intrinsic quality like the Criollo of Venezuela and Trinidad; the big demand for it is due to its use as the basis of cocoa mixtures, the higher grade cacaos being used in smaller quantities for improving the blend, in accordance with the quality required in the final manufactured product.

Towards the end of 1937 the majority of firms purchasing cocoa on the West Coast entered into an agreement regarding the terms of purchase, which was designed to prevent competition raising the local price above world price. The African growers, however, considered this to be detrimental to their interests. Cocoa was withheld from the market by growers in the Gold Coast and in Nigeria, who showed a remarkable degree of unanimity in what they considered to be their interests, and a Commission of Inquiry was appointed by the Colonial Office to examine and report on the marketing of cocoa in the Gold Coast and Nigeria, with special reference to the buying agreement entered into between certain firms. It is interesting to note that the agitation on the part of the peasant producers also took the form of a boycott of imported goods.¹

In French West Africa the estimated area annually cultivated with cacao is 1,500 square kilometres; the exports for the first nine months of 1937 were 42,000 tons, mainly from the Ivory Coast and the southern part of Dahomey. In the French Cameroons cultiva-

¹ *Parliamentary Debates, House of Commons*, vol. cccxxxv, no. 103, May 4, 1938, c. 836.

tion is still being extended and a programme of replacement of old plantations by new trees is in force; exports for 1936 were 23,808 metric tons.

In the Belgian Congo efforts made by *Inéac*¹ to form cacao plantations at Gazi have not as yet met with much response from native cultivators.

(1) Coffee

Coffee is scarcely used as yet by the Africans as a beverage and is grown almost entirely for sale. In Uganda, for example, local usage is confined to chewing the berries, which have a certain ceremonial importance and are offered to guests by persons of standing. The three major varieties,² *arabica*, *robusta*, and *liberica*, are native to Africa; *arabica* from the mountains of Abyssinia, *robusta* from the Congo, and *liberica* from the forests of West Africa. A minor variety, *stenophylla*, belongs to the highlands of Sierra Leone. The *arabica* variety produces the best quality coffee and is most widely cultivated, thriving best at heights above 2,000 feet. It needs better soil and more careful cultivation than the other varieties, which are hardier and do best from 2,000 feet down to sea level. *Robusta* produces better quality coffee than *liberica*, which is classed as coarse coffee, and grows best in humid climates, producing heavy crops of large berries.

Coffee has recently been encouraged in Nyasaland as a native crop by the distribution of *arabica* seedlings in certain areas, but it is held that the long dry season will prevent development on a large scale. As shown below, European production has now greatly declined. In Tanganyika, native and European production are not distinguished in official returns; the total area under coffee is estimated at 119,000 acres; and exports have increased from 9,251 tons in 1931 to 12,146 tons in 1936. Of this 6,504 tons, two-thirds *robusta* and one-third *arabica*, came from the Bukoba District where the crop is mostly native-grown. Owing to water shortage pulping is not done; the cherries are dried whole and the beans subsequently extracted by hullers. In the Moshi area native growers are organized in the Kilimanjaro Native Co-operative

¹ See below, p. 953.

² Imperial Economic Committee, *19th Report*, June 1930.

Union, and coffee grown in the Songea area is marketed by a co-operative society registered in 1936.¹ *Arabica* coffee-growing by Africans has recently been permitted in experimental areas in Kenya, in the Central and Nyanza Provinces; the full permissible acreage has not yet been reached. The Agricultural Department is conducting experiments with *robusta* coffee, as it is hoped that this type will prove a useful native cash crop.

Coffee cultivation in Uganda is carried on by both European planters and native peasants, principally in the Buganda, Western and Eastern Provinces, both *arabica* and *robusta* varieties being grown according to the suitability of climatic conditions. The share taken by Europeans in production is explained below; native interest in the crop began about 1922. The coffee industry has shown considerable expansion in recent years, exports having risen from 87,000 cwt. in 1932 to 228,783 in 1936. About three million seedlings are distributed annually by the Agricultural Department, of which 50 per cent. are said to survive after planting. In 1936 there were 17,066 acres of *arabica* under cultivation by natives out of a total of 23,252, and 27,171 acres of *robusta* out of a total of 34,457. Mulching with plantain and banana leaves is encouraged, and the results have been satisfactory not only in the effect on the coffee bushes but in arresting soil erosion.² Systems of pruning have been investigated and in one area natives trained as pruners are doing useful work. Instruction is also given to Africans in methods of control of the main coffee pests (antestia and mealy bug).

Production in British West Africa is confined to Sierra Leone and the Gold Coast: the former exports a few tons, the latter has so far consumed its production locally; the variety grown is *robusta*.

In the French territories *robusta* is the most widely grown variety. In French West Africa the total cultivated area of coffee is estimated at 700 square kilometres, and exports in the first nine months of 1937 amounted to 9,500 metric tons. In French Togoland cultivation is being stimulated; in 1936, 120,000 trees were planted in the southern division and 500,000 in the centre, and the export was 162 metric tons. In French Equatorial Africa,

¹ See Chap. XXI, p. 1473.

² See Chap. XVI, p. 1101.

robusta coffee planting is stimulated; plantations on the river Ubangi and the upper reaches of the Sangha are already in bearing, and in the first nine months of 1935, 820 metric tons were exported. In the French Cameroons native growers had planted over 4,500,000 trees by 1936 under administrative supervision and the export was 2,015 metric tons.

In the Belgian Congo coffee plantations made under the 'educative' system¹ covered 2,976 hectares by 1936, mainly in the Stanleyville Province; by 1936 a total of 627 hectares had been planted voluntarily by natives in the Costermansville Province. Coffee was introduced in Ruanda-Ürundi in 1931, and by 1936 over 18,000,000 trees had been planted; the banana groves with their accumulated humus have been found useful in connexion with the plantations. Production has risen from 70 metric tons in 1931 to 1,200 metric tons in 1936.

(m) *Palm Oil and Kernels*

Palm oil and palm kernels² are derived from the fruit of the oil palm; a fibrous pericarp contains the oil and covers the shell, which is cracked to obtain the palm kernel of commerce. In West Africa the edible pericarp oil is extracted by crude methods and the nuts are cracked by women and children; palm kernels are not used by the Africans, but exported to Europe for crushing, and the oil is used largely in the manufacture of margarine and soap. British West Africa is the largest producer in the world and, except for a few European plantations, production is in the hands of Africans.

In the early history of Nigeria palm oil and kernels were brought down the rivers and creeks to be traded on the coast; hence the origin of the name 'Oil Rivers' applied at one time to the Niger delta. The trade continued to develop as the country was opened up. It was thought at one time that the industry was so well established as to be unassailable, but about 1922 the exportation of an oil with a lower percentage of free fatty acid than the Nigerian product was begun from Sumatra and Malaya. The

¹ See Chap. XI, pp. 633-5.

² Empire Marketing Board, *Survey of Vegetable Oil Seeds and Oils*, vol. i, 'Oil Palm Products', June, 1932.

superior quality of the oil from the Dutch East Indies now makes it a strong competitor with that from British West Africa. A scheme for the improvement of existing palm groves, the planting and cultivation of selected types, and the use of hand-power presses to improve the quantity and quality of the oil, has been introduced by the Agricultural Department in Nigeria. The ultimate object is the complete replacement of wild by cultivated palms, but progress is necessarily slow as it is difficult to persuade the natives to depart from their old-established methods, and more difficult still to make them realize the dangers from outside competition. They are averse from cutting down old trees, and by native custom this cannot be done without the consent of all members of the group which jointly owns the plantation. In 1928 there were only six native owners cultivating 21 acres of oil palms under the scheme, while in 1936 there were 2,278 owners of 4,172 acres; but the rate of progress will not be regarded as satisfactory until it reaches 10,000 acres per annum. The Agricultural Department's farms are said to be unable to produce adequate supplies of seed, the germination of which is slow and uncertain. The production of palm oil entails a considerable amount of labour and is influenced by prices, years of low prices showing definite declines in quantities exported, and in order to compete with the East, exporting companies have installed bulking plants at several ports.

It was thought at one time that the future of the industry lay in the establishment of central oil mills to treat raw material purchased from the natives, but, as shown elsewhere, the scheme proved unsuccessful.¹ To encourage the use of the hand press, the Cultivated Oil Palm Ordinance² provides for a rebate of the export tax to those owners of plantations who use a press; in 1932 there were 58 presses in use, and by March 1937 the number had risen to 453. The native administrations actively assist in schemes for the improvement of the industry.

As little use is made locally of palm kernels the export figure—386,145 tons in 1936—represents almost the total annual production.

In the Gold Coast oil-palm products were the staple agricultural export before the development of the cacao industry.

¹ See Chap. XX, p. 1402.

² No. 17 of 1935.

Falling prices and the superior attractions of cacao cultivation caused the oil-palm industry to decline, and as recently as 1933 exports fell to 10 tons of oil and 2,493 tons of kernels; in 1936 exports rose to 442 tons of palm oil and 12,562 tons of palm kernels. The industry is said to be capable of considerable expansion by fuller exploitation of existing palm-bearing areas, but the cocoa trade is found more profitable, nor would labour be available for the less popular industry at the present time. It appears, however, that much could be done to prepare for expansion by organizing the thinning and replanting of existing palm groves, by supplying improved planting material, and introducing better oil-extraction methods, on the lines which have proved successful in Nigeria. There are two power mills in existence which are capable of dealing with increased supplies of raw material. The production of palm oil for consumption in parts of the country which do not carry oil palms is probably of greater importance than the export trade, owing to its dietetic value to the native population.

The importance of the oil palm to Sierra Leone is reflected in the record export of 84,578 tons of palm kernels in 1936, in addition to 1,222 tons of palm oil, and the export duty on kernels provides considerable revenue to the colony. The small proportion of oil to kernels exported indicates that there is a large consumption of palm oil for food purposes. The fruit of the indigenous Sierra Leone palm yields relatively little oil, breeding is now confined to imported varieties, and it would seem that an extensive system of district nurseries is necessary if the inferior palms are to be replaced.

In French West Africa the estimated annual production of palm nuts and palm oil is 120,000 metric tons. The principal producing areas are the Ivory Coast and Dahomey, and in the latter thirty machines for breaking the kernels are in use. In 1937 proposals were made for the protection and improvement of selected areas of wild palm plantations and the increased provision of centres for treatment and of means of transport.

In French Togoland the oil palm is an important source of revenue in the southern areas. Production of palm nuts in 1936, at 21,505 metric tons, represented 40 per cent. of the total production

for the territory. Palm oil exports reached a maximum of 3,348 metric tons in 1924; the 1936 figure was 3,281. Twenty-two mechanical crushers, provided by the local *sociétés de prévoyance*,¹ are in use, of which twenty have been mounted on lorries and can be moved from village to village. French Equatorial Africa produced, in the first nine months of 1935, 3,200 metric tons of palm oil and 8,000 metric tons of kernels. In the Cameroons palm products continue to be obtained principally from wild palms; administrative assistance in production has been concentrated on the provision, also through the medium of the local *sociétés*, of mechanical crushers and presses. In 1936 exports were 44,302 metric tons of palm nuts and 10,263 metric tons of oil.

In parts of the Belgian Congo the oil palm has always been important in native economy as a source of food and other products, and large areas have at different times been planted and then abandoned. It is now held that it is necessary to produce a better quality product than is obtainable by native methods, and since 1935 a campaign of agricultural instruction, accompanied by the distribution of selected seed, has been directed to this end. In 1935 and 1936, 5,292 hectares were planted under this scheme, but it has met with difficulties arising from the failure of the native cultivators to appreciate the need for new methods.

(n) *Coco-nuts and Copra*²

The coco-nut palm has a wide distribution throughout Africa, and in many territories the coco-nut is an important food crop. The coco-nut palm thrives best near the sea, but will grow well inland at elevations up to about 1,500 feet. It is subject to a number of pests such as scale and coco-nut beetle, which may at times assume serious proportions, and there appears to be no cure for the disease of bud-rot which kills the palm. Coco-nut palms in Africa are cultivated only when grown in plantations, and even then the cultivation consists mainly of keeping down grass and undergrowth. In Tanganyika coco-nut growing is confined to the

¹ See Chap. XXI, pp. 1477 ff.

² See Empire Marketing Board, *Survey of Oil Seeds and Vegetable Oils*, vol. ii, 'Coco-nut Palm Products', 1932.

coastal belt, where Europeans, Indians, Arabs, and natives participate in the industry. There is a considerable consumption of coco-nuts for food, and copra is used by local soap factories; also whole nuts are exported to Mombasa and Zanzibar. The amount of copra exported in 1936 was 7,458 tons: it is classed as 'fair merchantable' on the European market. Efforts are being made to improve the product by the introduction of simple drying-kilns. In the Gold Coast the copra industry is making progress in the coastal area, production having reached 2,000 tons per annum. The use of drying-kilns is essential in this area of heavy rainfall and high atmospheric humidity; and the Department of Agriculture is rendering technical assistance to stimulate the industry. French West Africa has an average production of 1,000 metric tons of copra from a planted area of 100 square kilometres. The export in 1935 was 332 metric tons. In French Togoland coco-nut coastal plantations extend between the sea and the lagoons, and the cultivation of the palm is stimulated by the administration. Between 1933 and 1936, 575,000 palms were planted, and exports of copra in 1936 reached 5,656 metric tons.

(o) *Tobacco*

Tobacco has a wide range of cultivation, from temperate to tropical climates, but successful production is restricted by a peculiar sensitiveness to soil and climate, which is so far imperfectly understood; if certain natural conditions are not present during cultivation, the particular quality desired cannot be attained.

Coarse native tobacco is grown on the outskirts of most villages throughout Africa. The leaves are dried and rolled into balls, or ground into snuff. In some districts, such as in the mining areas of the Congo and Northern Rhodesia, there is considerable traffic in the product.

The cultivation and preparation of tobacco suitable for the home market is a highly specialized business and the progress made by native producers is remarkable. In Nyasaland, tobacco, first planted in 1889 and exported in 1893, is grown by Europeans and natives in a proportion which may be taken as about one to five. The production for 1936 amounted to 16,484,160 lb. and

the export was 13,391,541 lb. The native product is fire-cured and that of the Europeans is mostly flue-cured. The market was originally the Union of South Africa, but tariffs enforced a change of market to the United Kingdom, and in 1936 only 199,649 lb. were exported elsewhere. The Imperial Tobacco Company, which established a factory at Limbe in 1908, buys the greater part of the crop. It is estimated that there are about 33,000 acres under native cultivation; the number of registered native growers in 1936 was 53,596. The growth of small crops of tobacco is easily combined with work in food gardens, and this no doubt accounts for the rapid increase in native production since it began about the year 1924. In Tanganyika fire-cured tobacco is produced by native growers in Songea. Total production, including that on European estates, increased between 1931 and 1935 from 19,360 lb. to 437,000 lb. The Department of Agriculture has established demonstration farms and nurseries for rearing seedlings for distribution and assists in marketing the crop, and growers are encouraged to form their own nurseries and rear their own seedlings from seed supplied by the department. A co-operative marketing society was registered in 1936. The tobacco, which is Virginian, approximates to the Nyasaland product, and buying grades have been fixed to maintain the quality.

In Uganda it was not until 1925 that serious consideration was given to tobacco as an export crop, and in 1927, 1,631 lb. was produced from the Bunyoro area where in 1934 production reached very nearly 1,500,000 lb. Production in the West Nile area was started in 1931 and in 1934 amounted to 159,830 lb. The effect of production and local manufacture has been to reduce imports of manufactured tobacco from 606,182 lb. in 1928 to 298,037 lb. in 1935. There is now a considerable export of unmanufactured tobacco to Europe, amounting to 228,783 lb. in 1936, and a market for locally manufactured cigarettes and tobacco in Kenya and Tanganyika. Production is almost entirely in the hands of natives and is supervised throughout. Seed is issued from the Tobacco Experiment Station at Bulindi and seedlings are reared at central nurseries under the supervision of agricultural instructors. There is a government reconditioning and packing plant at Masindi and

tobacco factories at Jinja and Kampala. A Tobacco Advisory Committee appointed in 1936 to review the position of the industry advised modifications in marketing to suit the needs of local manufacturers and of exporters of leaf. The varieties cultivated are Blue Pryor and Western for fire-curing, and Amorella for air-curing, and the yield is estimated at 100 to 500 lb. per acre. In West Africa, as in most other territories, coarse tobacco is grown for local use, and in the Gold Coast the natives are assisted in producing black leaf tobacco to meet a local demand. In Nigeria a tobacco company in the Ilorin Province, the main producing area, buys native tobacco.

(p) *Fruits*

In Tanganyika the possibility of developing a citrus industry is under investigation and trial shipments have been made to London and India. In Kenya a monopoly for the export of cashew nuts has been granted in order to try to establish the trade in this product as a minor industry. Exports are mostly to America, but there is said to be a good market in South Africa.

In Nigeria citrus is grown by natives in the area just south of the Niger and the first small consignment of oranges was made in 1932-3; during the 1935-6 season, from September to January, 1,709 cases were sent to England. The green Nigerian orange can only command a market in England when supplies from elsewhere are scarce; the costs of production are low, but are counterbalanced by freight and sale charges. A wide range of varieties has been introduced from several countries in the hope that one suited to local conditions and producing a superior quality of fruit may be found. It is considered that there are prospects for the development of a native grapefruit industry; a standard type is to be approved for planting and budded planting material will be distributed to approved farmers. Consideration has also been given to the export of fresh pineapples.

From the Gold Coast some shipments of oranges have been made by private individuals, but it is held that further selection of suitable varieties is necessary. A recent development has been the establishment of the lime-juice industry at Abakrampa, where a factory is attempting to deal with the produce of about 2,000

acres yielding at the rate of about 8 tons of fruit per acre when in full bearing. The principal product is raw lime juice, of which 355,826 gallons were exported during the 1935-6 season; 6,800 lb. of hand-pressed lime oil and 45 tons of fresh fruit were also exported. The supply of fruit is now equal to demand, and it is held that restriction in further planting is necessary.

III. AGRICULTURAL PRODUCTION BY EUROPEANS

While, as we have seen, native agricultural production is that of small peasant farmers who are, in most cases, primarily engaged in growing sufficient food to feed themselves and who, even where a purely cash crop is grown, mix its cultivation with that of food crops, European agriculture is developed either by individual employers of native labour or by companies or individuals buying produce from small native growers. The chief characteristic of the European agricultural enterprise is indeed its dependence on an easy supply of cheap native labour rather than on machinery. The policies of the various governments with regard to the settlement of non-natives and the extent to which land has been alienated to them are discussed elsewhere,¹ as also are the problems arising from the systems of European agriculture² and the extent to which it is subsidized from public funds. The purpose of the following pages is to give a description of the extent of European activity and some account of the main crops grown.

In the Union of South Africa about 173,000 Europeans are actively engaged in commercial agriculture, which is almost entirely in European hands. Only 5 per cent. of the total land area is cultivated and only 15 per cent. can be classed as arable land capable of being cultivated. Most of the remainder is suitable for pasturage of some kind. The main products are maize, wheat, fruit, sugar, and tobacco. In South-West Africa agriculture is of minor importance compared with stock-farming. In Swaziland a large proportion of the land is under European ownership, and is utilized for stock-raising, supplemented by tobacco, cotton, and maize. Lack of capital hinders the development of European agriculture.

¹ See Chap. XII, *passim*.

² See Chap. XX, pp. 1361 ff., and S. H. Frankel, *Capital Investment in Africa*, 1938, chap. iv.

In Southern Rhodesia there has been a reduction from 4,541 in 1931 to 4,305 in 1935 in the number of Europeans actively engaged in farming; the main crops are maize, tobacco, cotton, and groundnuts.

Northern Rhodesia has a small number of settlers engaged in the production of maize, tobacco, coffee, and wheat.¹ In Nyasaland European agriculture is giving way to native production. In Tanganyika the plantation crops are sisal, coffee, maize, and tobacco. In Kenya European exceed native exports, the principal products being coffee, sisal, tea, and maize, with smaller quantities of sugar, wheat, potatoes, beans, pyrethrum, and essential oils. The pyrethrum crop is grown at altitudes of 7,000 feet and over, and in 1936 the exports amounted to 20,798 cwt. Grants to enable investigation to be carried out in connexion with this crop and with the essential oil industry have been made from the Colonial Development Fund. The export of essential oils amounted in 1936 to 2,640 gallons.

In Uganda some coffee, one sisal estate, and all tea and rubber planting are in European hands; the acreage of rubber estates is estimated at 11,545. Exports of rubber ceased in 1932 owing to the fall in price, but amounted to 1,157,500 lb. in 1936. Nigeria has three large European-owned rubber plantations, and there are several in the British Cameroons, in addition to plantations of cacao, oil palms, and bananas. In the Gold Coast there is one rubber plantation. In 1936 the exports of rubber, mostly *hevea* with a small quantity of West African *funtumia*, from Nigeria and the Cameroons amounted to 4,345 tons, and from the Gold Coast to 527 tons. In Sierra Leone a company has taken over a palm plantation originally established by government. In French West Africa there are large banana plantations and smaller areas cultivated by non-natives with coffee, sisal, kola, and rice, mainly in the Ivory Coast and Dahomey. In French Equatorial Africa the *Compagnie Forestière Sangha Oubanghi* held until 1937 a large concession for the export of wild rubber for the Ubanghi-Shari region, but there are no other European plantations. In the French Cameroons there were three rubber plantations in 1937, and cacao is grown by ten companies. In the Belgian Congo the

¹ See below, pp. 920 ff., for further details of these and other important crops.

Huileries Company has a large palm concession in which they are developing plantations.¹ The company obtains raw material partly from wild fruit collected by natives and partly from plantations. The total export of palm products from the territory in 1936 was 92,373 metric tons of nuts and 59,960 metric tons of oil. Rubber plantations are 5,706 hectares in extent, and exports in 1936 were 791 metric tons. It is expected that there will be considerable development in the growing of *hevea*. Bananas and other fruits, coffee, rubber, cinchona, and tea are also produced in the Belgian Congo by Europeans.

(a) *Maize*

In the Union the total acreage under maize is estimated at 9,250,000 acres, of which fully 6,000,000 are European-owned, and production in 1936 amounted to over 18,000,000 bags of 200 lb. each. Production increased considerably after the Boer War, when the depleted animal population caused the farmer to turn to grain production. Periods of high prices stimulated production, but with the drop in prices after 1930 the growing of maize for export has had to be subsidized in order to be profitable. A series of mealie control acts from 1931-5 provided for a control board and for the compulsory exportation of a quota of maize; and resulted in raising the price obtained for maize consumed in the Union above that for grain for export. This policy also increases the cost of feeding cattle, and the Department of Agriculture urges the combination of stock farming with maize growing. An alcohol factory, established at Germiston, will absorb a small proportion of the crop.

In Southern Rhodesia yields are about twice as high as in the Union, but owing to the fall in prices the area under maize has declined in recent years, and is now about 200,000 acres. There are about 2,000 growers. The Maize Control Board created in 1931 pools maize collected from various co-operative organizations, which in 1936 surrendered 653,481 bags to the Board, or 64.7 per cent. of the export pool, of which 249,294 bags were shipped overseas, 103,811 bags were sold to farmer consumers at reduced rates, 43,734 bags were sold at a rebated price to feeders

¹ See Chap. XII, p. 793.

of cattle for the chilled meat trade, and 28,000 bags were exported to adjacent territories. Cultural methods of control of striga (witch weed) are employed and trap crops planted; one of the most effective is Rhodesian Sudan, an indigenous perennial grass, while Amber Cane and White Kaffir corn serve as traps and green manures. A new disease-resistant strain of maize has been bred at the Hillside Station.

In Northern Rhodesia total exports of maize for 1936 amounted to 424,000 bags; of this 274,000 were produced by Europeans.¹ An export quota system is in force here also. In Tanganyika there are some European maize plantations on the slopes of Mount Kilimanjaro, and European maize production in 1936 was estimated at 400 tons.

(b) *Wheat*

The date of the introduction of wheat to the Union is that of the first colonization—1652. A protective tariff on imported wheat was imposed in 1930, and in 1931-2 production equalled local consumption. In 1935 production and consumption were estimated at 6,059,000 bags and 5,000,000 bags respectively and the export price is now below the local value. The Wheat Industry Control Act of 1935 set up a control board and provided for the storage of wheat during years of surplus production and the payment of compensation to holders for losses due to depreciation or decline in prices. Funds for this purpose are derived from a levy on milled wheat.

In Southern Rhodesia production rose from 5,000 bags in 1928 to 63,000 in 1936, but still does not meet local requirements. In Northern Rhodesia wheat is grown almost entirely under irrigation; the crop was 18,000 bags (of 200 lb.) in 1935 and 11,121 bags in 1936, a bad year for rust; in 1937 this figure was further reduced to 5,504 bags, owing to water-shortage. The surplus is exported to Southern Rhodesia.

Elsewhere the cultivation of wheat is restricted by climatic conditions. There is no wheat grown in West Africa, and in East Africa production is confined to the highlands. The area under wheat in Kenya, 48,054 acres in 1935-6, is situated mostly at alti-

¹ See Chap. XX, p. 1387.

tudes of 7,000 to 9,000 feet, but suitable varieties can be grown at considerably lower levels. The total sold in the 1935-6 season was 151,305 bags, and exports in 1936 were 45,996 cwt. of wheat and 61,875 cwt. of wheat flour. The types of wheat at present grown in Kenya have been evolved by the Agricultural Department. Damage by rust reduces both the yield and quality of the crop and research is directed towards breeding rust-resisting varieties, but it is said to be difficult to find a strain that will be resistant to all four forms of rust and yet up to the present standard in quality. Moreover, different altitudes require different varieties.

(c) *Cotton*

Cotton growing has been tried by European farmers in South Africa for many years, but production remains on a comparatively small scale; in 1910-11 it was about 30 bales of 400 lb. each; in 1929-30 it reached 15,000 bales, but fell to 2,500 bales in 1934-5.

The crop is subsidized and an export levy finances the Central Co-operative Cotton Exchange, Ltd., of Durban, which handles about 30 per cent. of the crop.

In Southern Rhodesia cotton growing, stimulated by high prices, received an impetus in 1924-5, and production rose to over 5,000 bales in 1925-6, but after the serious fall in price in 1925 and 1926 most farmers discontinued growing. Production is now on a very small scale; only 2,004 acres were planted in 1936, yielding 329 bales (400 lb.) of lint. A Cotton Research and Industry Board was appointed in 1936 to liquidate and take over the three co-operative ginneries and operate them as required, to foster cotton growing as a European and as a native industry, and to market European cotton and purchase and market native-grown cotton. Bollworms, stainers, and jassids are the principal pests.

In Northern Rhodesia an attempt is being made to establish cotton, and 205 Europeans in the Southern Province have undertaken trials. Ultimate success is still doubtful, but there are prospects of establishing a small industry in areas near the railway line where soils are suitable.

In Nyasaland cotton, introduced as a plantation crop in 1900,

has now become almost entirely a native crop, only 1,997 acres being under cultivation by Europeans in 1936.

In Tanganyika about 10 per cent. (6,200 bales in 1936) of the total cotton export is produced by non-natives, mostly in the Eastern and Tanga Provinces.

(d) *Coffee*

In Northern Rhodesia planters in the Abercorn District have 416 acres under coffee, mostly the Blue Mountain variety. This is a young industry which in 1935 produced 627 cwt. and exported 474 cwt. A co-operative society has recently been formed to deal with the marketing of the entire crop and a small and promising factory has been established at Abercorn.

Coffee planting in Nyasaland dates from 1878; by 1891 there was a flourishing industry in the Mlanje District, and in 1900 the peak was reached with 17,000 acres under cultivation and an export of 2,000,000 lb. Since then the industry has declined, and in 1936 there were only 837 acres under European cultivation.

Coffee was first grown by Europeans in Kenya about thirty years ago; it is now cultivated in suitable areas throughout the highlands. Between 1909 and 1919 exports rose from 169 cwt. to 71,545 cwt.; between 1932 and 1936 the average export was nearly 300,000 cwt.; in 1936 there were 978 registered coffee estates and a total area under coffee of 101,234 acres. *Arabica* and *robusta* varieties are used according to soil and climatic conditions. The mealy bug and berry disease have been specially studied by the Department of Agriculture, and the need to maintain quality in the face of competition calls for the fullest investigation.¹ The commercial side of the industry is controlled by the Kenya Coffee Board, coffee curing and cleaning factories have been established at Nairobi, Kitale, and Mombasa, and recently sales by public auction in Nairobi have become a regular feature of the trade, so that now coffee can be shipped direct to overseas buyers. In Uganda, where coffee growing is mostly in the hands of Africans,² European plantations accounted for 6,028 acres of *arabica* and 6,663 acres of *robusta*, and Indian for 158 acres of *arabica* and 623

¹ See below, pp. 943 ff.

² See above, p. 910.

of *robusta*. French Guinea has a small non-native production of coffee. In French Equatorial Africa coffee plantations have been established along the Sangha and Ubangi rivers; exports were expected to exceed 1,200 metric tons in 1936. In the French Cameroons fifteen companies had coffee plantations in 1937. In the Belgian Congo, 56,258 hectares were planted with coffee by Europeans in 1936, and production was 15,080 metric tons of *robusta*, and 2,995 metric tons of *arabica*.

(e) *Tea*

In Nyasaland first attempts to introduce tea about 1878 were not successful, but ten years later the crop was established. Production was not appreciable until the beginning of the present century, but progress has been steady; thus in 1911-12 the acreage under cultivation was 2,593 and the exports 43,876 lb.; in 1936 the figures were 16,346 acres and 7,706,088 lb. respectively. Production is confined to the two districts of Mlanje and Cholo, where rainfall is above the country's average, and under an international restriction scheme the acreage is limited to 17,700 acres up to March 1938. There is a cess on exported tea, the proceeds of which are used by the Nyasaland Tea Association for the benefit of the industry.

In Tanganyika a tea industry is being developed with prospects of success¹ in the Usambaras and Southern Highlands, and in 1936 production amounted to about 106,000 lb. Four tea factories have been established and a growers' association formed. As in Nyasaland, expansion is controlled by the international scheme. In Kenya the production of tea has risen rapidly in the past few years, from 930,209 lb. in 1930-1 to 9,043,124 lb. in 1936-7. The international scheme restricts the area under cultivation and expansion is also limited by climatic conditions. In Uganda tea estates occupied 2,139 acres in 1936 and produced 180,000 lb. for local consumption and 84,432 lb. for export.

One tea plantation exists in the French Cameroons, and in 1936 a company was formed to open a tea plantation near Lake Kivu in the Belgian Congo.

¹ H. H. Mann, *Report on Tea Cultivation in the Tanganyika Territory and its Development*, 1933.

(f) Tobacco

Tobacco growing in South Africa dates back to the early colonial days. The original product was the well-known Boer tobacco prepared by fermenting, rolling, and coiling the leaf. Most of the crop is now sold to manufacturers for the production of cigarettes and pipe tobacco for consumption in the Union, and until quite recently the greater portion of the crop was air-cured. Flue-curing was not taken up to any extent till 1930. Production has varied; the maximum was 23,000,000 lb. in 1928, and it is now about 16,000,000 lb. Irrigation is commonly used and the principal area of production is the western Transvaal. The government encourages co-operation in the marketing of tobacco and protects the industry by an import duty on unmanufactured tobacco from territories other than the Rhodesias. There is also an export bounty at rates varying according to grade.

Swaziland in 1936 exported 282,735 lb. of tobacco through a co-operative society with 300 European members.

In Southern Rhodesia the tobacco industry, which was started by the pioneer settlers in 1895 and is still in the hands of European planters, yields some £600,000 a year. In 1927 the acreage was 30,164 and production 19,000,000 lb.; in 1936, 41,497 acres produced 22,401,707 lb., of which 21,717,898 were Virginia type and 683,809 Turkish type. Exports of unmanufactured tobacco in 1936 amounted to 18,367,920 lb., of which 13,500,000 lb. went to the United Kingdom, 2,000,000 to the Union, and 2,500,000 to other countries. About 95 per cent. of the tobacco is flue-cured and is classed as the best quality African tobacco.

In Northern Rhodesia, where production is also in non-native hands, Virginia tobacco occupies over 3,400 acres, mostly in the Fort Jameson area. Exports for 1936 were absorbed by the United Kingdom—581,000 lb., the Union of South Africa—350,000 lb., and Southern Rhodesia—155,000 lb. A Tobacco Board safeguards the interests of the industry and the Northern Rhodesia Tobacco Co-operative Society¹ has been organized to facilitate marketing. In Nyasaland tobacco growing is now largely in the hands of natives;² the European area under cultivation

¹ See Chap. XXI, p. 1469.

² See above, p. 915.

in 1936 was 7,349 acres. In Tanganyika the output of the European estates in Iringa for 1935 was 152,000 lb. of Virginian and 4,000 lb. of Turkish tobacco, the bulk of which is sold to Dar-es-Salaam manufacturers.

(g) *Sisal*

The cultivation of sisal as an economic crop is confined to East Africa; it grows satisfactorily at a low altitude in moist conditions and thrives on the sandy soils of coastal areas. In Tanganyika the estimated area under sisal in 1935 was 276,500 acres, mostly in the coastal belt near Tanga, and the product accounts for half the tonnage of agricultural exports from the territory. Despite low prices export has risen from 60,554 tons of sisal fibre in 1932 to 80,559 tons in 1936, of which some 20,000 tons are produced by Indians. During this period production costs had to be reduced to a minimum, but the sudden rise in price to £28 per ton in 1935-6 gave great assistance to the industry. It is held that the capacity of the industry for expansion is limited only by the supply of available labour, and at present there is said to be some difficulty in obtaining a sufficient supply; the unpleasant nature of this crop makes the need for attractive conditions of labour particularly important. In 1934 a new sisal experimental station was opened at Mlingano to work in conjunction with Amani.

Sisal has been grown in Kenya from its early days, but it was not until 1915 that export reached the moderate level of 1,652 tons. In the twenty years since then there has been a steady and substantial increase, and in 1936 exports reached 34,746 tons. Production is in the hands of European companies operating estates on a large scale with their own decorticating plants. In contrast with the situation in Tanganyika, the greater part of the acreage in Kenya is in the highlands. Investigations on systems of planting and improvement of fibre extraction are carried out on the estates by the owning companies, and the Kenya crop is remarkably free from pests and diseases. In Uganda a sisal estate of 5,000 acres in Bunyoro produced 574 tons in 1935 and 1,457 tons in 1936.

(h) Fruit

In the Union the first fresh fruit was exported in 1888. Oranges were introduced from St. Helena soon after the occupation of the Cape in 1652, but exports were comparatively small until after the War, when the good prices realized for South African fruit gave a decided impetus to the industry. Expansion began in 1918, when a large number of trees were planted, many of which proved worthless, as little care had been exercised in bud selection. The industry receives special concessions in respect of its export trade.

In 1936, 17,450,956 lb. of dried fruit were exported, 155,189 tons of citrus, and 91,158 tons of deciduous fruit.

The production of dried fruit is of long standing in South Africa and after the War there was a rapid expansion. The principal producing area is in the Cape Province.

There is a certain amount of citrus growing inland and north of Capetown, but the principal areas of production are around Port Elizabeth and in north and east Transvaal. In recent years the expansion in grapefruit production has exceeded that in orange production. Citrus growing is carried out on estates of varying size and in all cases irrigation is necessary. After 1920 a considerable number of local citrus fruit marketing associations were organized and in 1926 they united to form the South African Co-operative Citrus Exchange Ltd., which is financed from a levy on the exported fruit. The local associations own most of the co-operative packing houses and, if required to do so, fumigate and pick the fruit for members. The industry requires government assistance, as the prevailing price leaves only a small margin of profit, and in 1936 concessions were granted in the rates for pre-cooling, transport, handling and inspection, and also in railage charges.

South Africa became known as a grape and wine producer two centuries ago, when Capetown was a port of call for ships bound for the Indies, but it was not until refrigeration in ships was improved in the early part of this century that the exportation of deciduous fruit from the Capetown area assumed importance. Rapid expansion began after 1926. The disposal of supplies is becoming difficult in the face of increasing competition on the

British market, and tariff policies in continental countries. The extent of grape production can be gauged from the fact that an export of 34,805 tons in 1935-6 represents only about 10 per cent. of the total production; about 80 per cent. is used for wine and the other 10 per cent. for drying. The principal grape-growing district is near Capetown, where the rainfall is sufficient and irrigation unnecessary. The expansion in vine culture is largely attributed to the enactment of the Wine and Spirit Control Act of 1924, which gave the Co-operative Wine Growers Association (the KWV) of South Africa full control over the disposal of distilling wine.

The principal areas for other deciduous fruits lie inland from Capetown and along the south coast, and there are two important irrigated areas north of Port Elizabeth. The marketing of fruit is organized through local associations which are members of the South African Co-operative Deciduous Exchange Ltd., financed from a levy on exported fruit. It is estimated that there are about 2,000 commercial growers of deciduous fruit in the Union, but only about 750 produce for export, and about 40 per cent. of the export fruit is handled by the Exchange.

The government concessions take the form of substantial rebates of railway rates and of charges for pre-cooling and inspection. In Southern Rhodesia the citrus industry is mostly in the hands of one company and expansion is hampered by low prices. In 1916, 1,336 cases were exported and in 1936, 117,940 cases.

Elsewhere in Africa the fruit trade is unimportant and conditions are not generally favourable to the development of citrus or other fruit industries, except bananas. Bananas are produced on European-owned plantations in the Ivory Coast, and in the French and British Cameroons where the export is mainly from the German-owned plantations; in 1936, 49,605 tons were exported and there is a regular service for this product. In the Belgian Congo, apple, almond, and peach orchards planted in 1934-5 have been successful in the Katanga.

(i) *Sugar*

Sugar production in the Union is confined to a narrow strip along the coast of Natal Province, about 235 miles long and 10 to

15 miles wide. One-third of the crop is produced by milling companies owning large estates and the other two-thirds by about 600 independent planters with estates averaging 300 to 400 acres, although some extend to about 1,600 acres. The industry dates from 1849; after 1880 it expanded on account of the opening of the mines and a further increase took place when the Anglo-Boer War produced an increase in local demand. Government policies and preferences have accounted for subsequent expansion. Production increased from less than 100,000 short tons in 1912 to 417,318 in the 1935-6 season. In spite of increased local consumption, it is still necessary to export over 50 per cent. of the crop at world prices, which is only possible owing to the high internal price maintained through protection.

In Kenya sugar is grown principally by Europeans and to a lesser extent by Indians. Although the quantity produced by the mills is considerable—about 15,000 tons in 1936, of which 6,000 tons were exported—cultivation is of local interest, and in order to ensure the markets of Kenya for the industry it is protected by tariff.

IV. ANIMAL HUSBANDRY

(a) *General*

The geographical distribution of domestic cattle is determined in Africa by the existence of the tsetse fly; as shown below, this means in effect that in the Rhodesias and in East and Central Africa there are large areas in which domestic cattle are maintained only with great difficulty, or not at all, and that in the southern areas of West Africa the only cattle found are the small dwarf shorthorns, which appear able to resist the trypanosome.¹

Purely pastoral nomadic tribes are found principally in the savannah region on the southern border of the Sahara, but a much larger number combine stock-rearing with cultivation. Most tribes also own sheep and goats, the latter in greater numbers than cattle; goats also may play their part in marriage and other social customs: with the Kikuyu, for example, they take the place of cattle in this respect. A small variety of chicken is found in most native villages and they play an important part both as a food and

¹ See below, pp. 932 ff.

in magical rites. The sale of chicken, often carried great distances to markets, is a source of relatively considerable revenue. In Natal and the Ciskei, natives are undertaking poultry breeding, which appears to be a form of industry suited to peasant farmers.

Both in South and East Africa European agriculture in its early stages relied mainly on stock-rearing, which later tended to be abandoned in favour of cultivation. In the Union of South Africa, however, some authorities have expressed the opinion in recent years that the country, with the exception of small areas where special crops such as citrus can be grown with profit, is better suited for animal husbandry. It is held that more than four-fifths of the total area of the territory can be used only for grazing, and that animal husbandry has the further advantage to a country of predominantly poor soil that it can produce the manure necessary for enriching the grass lands, or assisting in mixed farming.¹ The same consideration applies, in an even more marked degree, to the mandated area of South-West Africa. There are throughout East Africa certain areas which, whether viewed as purely native or fitted for European colonization, are primarily suited for stock-raising rather than for agriculture, either because of the character of the climate and soil or on account of difficulties of transport. Unlike other agricultural produce, cattle 'convey themselves to their market'.

The indigenous African cattle appear to be derived from three original stocks. The Hamitic longhorn probably descended from the giant-horned wild ox of the Nile valley (*Bos primigenius*); probably the surviving strain nearest to the original type is the N'Dama cattle, which have been extensively introduced into West Africa. The *Brachyceros* or the shorthorn, possibly derived from the *Bos primigenius* or a small ancestor, came to Africa from Asia at the end of the neolithic era, and general fusion with the Hamitic longhorn resulted. The *Brachyceros* were dwarf cattle, and it is now thought that the dwarf cattle of the regions near the Gulf of Guinea represent, not a distinct breed, but a survival of the older form. The term 'West African shorthorn' does not represent a breed, but is used to describe the unhumped short-horned cattle of West Africa which are a mixture of Hamitic

¹ See H. D. Leppan, *Agricultural Policy in South Africa*, 1931.

longhorn, shorthorn, and zebu. The zebu are, broadly, humped cattle, and came to Africa more recently. They have not the same resistance to trypanosomiasis, but have better resistance to rinderpest.¹ The Afrikander cattle are the nearest to the pure zebu.

In South Africa a number of British breeds, notably the Ayrshire and Friesian, have been successfully acclimatized, and in all areas of European settlement introduced types have been crossed with indigenous stock. In South Africa good breeds for the beef industry have been developed by crossing with the Afrikander, and the Sussex type is said to give the best results. In Southern Rhodesia the three local types of native cattle have been crossed chiefly with Herefords and Aberdeen Angus, Devons and Shorthorns being also used. In Tanganyika, Friesian and Ayrshire cattle have been imported with a view to the production of a dairy type. In Kenya there are a number of high-grade herds of British dairy cattle established in the highlands. In French West Africa three European herds, the Charollaise, Normande, and Tarentaise, have been introduced with varying degrees of success. In the Belgian Congo shorthorn bulls have been crossed with the native type in the Uélé region. In the Lower Congo a breed imported from Angola has been crossed with Hereford, Devon, Ayrshire, Friesian, Breton, and Afrikander types.²

Native sheep are of many types; the majority are hairy and fat-tailed. Merino sheep were established in the Cape Colony in 1812, and the number in South Africa is now second only to that of Australia. Blackhead Persians, which can thrive on land too poor for merinos, were introduced later. Mutton-breed rams such as Dorset horn, Southdown, Leicester, and Romney Marsh have recently been imported for crossing with local varieties. The native sheep industry of Basutoland is based on the merino; Karakal and Blackhead Persian have been introduced in South-West Africa, from which there is a large export of pelts. There are some merino herds in the drier parts of Kenya, such as Naivasha; in the wetter areas Romney Marsh are crossed with native sheep. Attempts to introduce merinos in Northern

¹ S. L. Stewart, *The Cattle of the Gold Coast*, 1937, and E. B. Worthington, op. cit., chap. xiv.

² See E. B. Worthington, op. cit., chap. xiv.

Nigeria were unsuccessful. Both the French and Belgian Governments have imported sheep. In French West Africa the Diré Company has a flock of some 2,000 merinos. In the Belgian Congo large flocks of merinos and Romney Marsh are naturalized at the government farm at Nioka in Ituri. Improvement work has been concentrated on the pastoral areas in the north-east and south-east. In Angola, Portuguese and French merinos and Rambouillet have been imported for breeding wool sheep, and Persian Blackheads from South Africa for mutton.

African goats are remarkable for their resistance to trypanosomiasis, their apparent immunity to tuberculosis, and their ability to obtain food in difficult conditions. Angora goats have been introduced in the Union of South Africa and Basutoland.

Native stock-rearing is characterized by the importance attached to numbers rather than quality, the Fulani being the only tribe who follow any principles in breeding. Cattle are grazed at will on the fallow land, individual rights to grazing areas being rarely recognized.¹ The problems of erosion following from tribal systems of grazing are discussed in a later chapter.²

(b) Animal Diseases and Preventive Measures³

The prevalence of animal diseases is a serious obstacle to the development of animal industry in Africa, particularly in view of the restriction of markets imposed by quarantine regulations. Of these trypanosomiasis, spread by the various species of tsetse-fly, is prevalent in an area bounded roughly on the north by a line from the mouth of the Senegal river through Lakes Chad and Rudolf to the coast of Italian Somaliland, and on the south by one which bisects Angola and then runs southward along the boundary between that territory and Northern Rhodesia and then eastwards across Southern Rhodesia and Portuguese East Africa. It is estimated that 65 to 75 per cent. of this area is infested by fly. In Bechuanaland fly encroachment is driving cattle from well-watered to drier areas. In Southern Rhodesia fly is encroaching on areas which were freed from it by the destruction of game in the rinderpest epidemic of 1896, at a rate which some years ago was

¹ See Chap. XII, pp. 829 ff.

² See Chap. XVI, pp. 1066 ff.

³ For a fuller account see E. B. Worthington, *op. cit.*, chapters x and xiv, and map.

estimated at 1,000 square miles a year. Since 1918, when European farming areas were first invaded by it, a number of farms have been abandoned and more are threatened, and it is held by some authorities that further encroachments can only be prevented by the destruction of the game on which the fly feeds. At present organized destruction of game is carried out between the fly-free and the infected areas, and over 2,000 square miles have been cleared, but the method has met with criticism on the ground that the fly may also feed on the numerous small mammals which have not been destroyed.¹ In Bechuanaland similar methods are considered impossible owing to the great area involved and the sparse population. Trapping of flies has been carried out in Tanganyika, Zululand, and parts of the Congo, but its chief value appears to be that of helping to clear up isolated patches of fly which have been attacked by more wholesale methods.²

The treatment of animals infected with trypanosomiasis with the compound 'Surfen C' synthesized in the Bayer laboratories has given good results. No certain method of immunization has yet been found, but a process is under trial by Dr. Claus Schilling, Director of the Robert Koch Institute in Berlin, who has carried out experiments at the government farm at Mpwapwa in Tanganyika. In Northern Rhodesia importance is attached to the development of resistance by satisfactory feeding. In West Africa it has been found that there are many local strains of trypanosome, immunity to one of which does not confer immunity to others, but the N'Dama appear most resistant to the different strains.

The question of importing cattle for breeding purposes is bound up with that of resistance to disease; imported cattle are more susceptible and the pasture is not generally of a quality to build up such resistance. For native stock, the better line at present would appear to be the improvement of indigenous breeds, to develop a useful dual-purpose animal needed for mixed farming.

Rinderpest entered Africa by way of the Nile towards the end of the last century. In 1896 an epidemic devastated the

¹ See R. W. Jack, *The Tsetse Fly Problem in Southern Rhodesia*, 1933, and 'Report of the Chief Entomologist for 1934', *Rhodesian Agricultural Journal*, Bulletin 962, 1935.

² For measures taken with regard to human trypanosomiasis (sleeping sickness), see Chap. XVII, pp. 1129-36.

cattle areas of eastern and southern Africa, and the disease is now found also in West Africa. Methods of immunization were first discovered in South Africa, and the disease is now under complete control in South Africa and the Rhodesias. The method most commonly adopted is simultaneous inoculation with virulent blood and anti-serum. Inoculation of herds is apt to be followed by a certain mortality from other diseases contracted during the period of lowered resistance, but this has been reduced in West Africa to 2.5 per cent. of inoculated animals and in Kenya to 1.5 per cent., and it is now the aim in most territories to immunize young animals while still healthy. In Northern Nigeria both Fulani and Hausa readily bring their herds to immunization camps and seem to appreciate that the initial losses are offset by the lifelong immunity to rinderpest of the majority of the herds. In the Gambia annual inoculation campaigns are carried out by veterinary officers seconded from Nigeria or the Gold Coast. In Kenya a method of vaccination with extracts of organs of diseased cattle (spleen vaccine), first used by Boynton in the Philippines in 1917, has been under trial since 1927. The vaccine prepared in this way remains potent for a long period and so can be used at a distance from the laboratory by stock owners on their farms and applied over large areas more rapidly than double inoculation.¹ It usually produces no reaction but it does not confer permanent immunity, and production is at present expensive. A cheaper type of vaccine is under trial at the research station at Marua in the French Cameroons. In Nigeria inactivated vaccine is used for the immunization of cattle entering this territory from the adjoining French colonies; the movement of such cattle is controlled by orders of the native administrations of the northern territories prohibiting their entry except at specified points. Spleen vaccine can also be used in emergencies to control outbreaks of rinderpest, and as a preliminary to double inoculation in the case of herds which are heavily infected with trypanosomiasis.

East Coast fever is found in all regions between Natal and the southern part of Italian Somaliland, and extends westward into the Belgian Congo; it is not found in West Africa. The discovery that the fever is a parasitic disease carried by ticks was made by

¹ J. Walker, 'Rinderpest Research in Kenya', *Agricultural Department Bulletin*, 8A, 1929.

Sir Arnold Theiler in 1904 at the Onderstepoort veterinary laboratory in South Africa.¹ No satisfactory method of immunization has been found, and the usual method of control is the dipping of stock at frequent intervals in order to remove the ticks. This is now a routine operation in large parts of East Africa, and is readily practised by natives. But in order to be fully effective this must be accompanied by fencing or other measures for the control of movements of stock.

Contagious pleuropneumonia is controlled by vaccination both in East and West Africa and in Kenya, where much work has been done on diagnosis and on the preparation of vaccines, and it has been eradicated from most European herds. In Northern Rhodesia it is enzootic in the Barotse Province, to which it is confined by means of a police cordon 146 miles long, and on the Angola border a buffer area established in 1934 is patrolled in order to prevent the infiltration of infected cattle. In 1936 an intensive vaccination campaign was undertaken from a field station established for the purpose in Sesheke District. In Tanganyika the disease is confined by quarantine measures, affecting some 116,000 cattle, to six areas in the Northern and Tanga Provinces; triple vaccination, the method recommended by the Kabete research laboratory, was tried in 1936, but is only practicable in specially favourable conditions. In Uganda an intensive campaign in 1926 eradicated this disease over a large area, but it is still enzootic in Karamoja, where quarantine measures are enforced. In Kenya control is rendered difficult among native tribes by the fact that natives set a high value on cattle which have recovered from the disease and are not readily persuaded to slaughter infected animals. In the Gold Coast the disease is spread by the smuggling of infected cattle over the French frontier, but it has been found to be controllable by a vaccine which gives immunity for about a year. In Nigeria prophylactic vaccination is unpopular with native owners, and vaccination campaigns can only be carried out when outbreaks occur.

Foot and mouth disease is usually less virulent in Africa than in Europe, but has attained serious proportions in Southern Rhodesia. Anthrax is widespread in native areas in the Union;

¹ See below, p. 946

it is the most important disease in Bechuanaland and is prevalent in Northern Rhodesia in the Zambesi and Kafue valleys; vaccination measures have not been pressed in the Zambesi area owing to the policy of concentrating on the eradication of bovine pleuropneumonia. In Tanganyika the disease occurs sporadically and is rarely reported except when cases of human infection occur. Vaccination, and the burning of carcasses in pits, are carried out as preventive measures. It is also serious in Ankole and the Masaka District of Buganda in Uganda. In Kenya annual vaccination is carried out in the settled areas.

Recent studies in Uganda indicate that bovine tuberculosis is more common than was previously supposed. In Nigeria this disease assumed serious proportions in 1936 and appears to have spread from the Cameroons. The white zebu cattle owned by the Fulani in the Northern Provinces are apparently immune.

Quarantine restrictions on the movement of cattle have had an important influence on the development of animal husbandry. The Cape Colony was closed to imports of cattle early in the present century, owing to an outbreak of East Coast fever in the Rhodesias and the Transvaal, and the Union continued the restriction after 1909. A quarantine market was opened in Johannesburg in 1912. In 1923 the quarantine regulations were relaxed, but were replaced by measures of direct protection, and they were reintroduced between 1932 and 1935 as the result of an outbreak of foot and mouth disease in Southern Rhodesia. The marketing of cattle from various territories in Northern Rhodesia and the Congo has been almost entirely determined by quarantine restrictions. Up to 1914 the requirements of both territories were supplied almost entirely from Barotseland. In 1914 exports from that area were prohibited owing to an outbreak of pleuropneumonia, and their place was taken by cattle from Ngamiland in Bechuanaland. At this time cattle from Southern Rhodesia were excluded from territories to the north on account of East Coast fever, but when the restrictions were withdrawn in 1922 this colony captured the Congo trade. After the outbreak of foot and mouth disease in Southern Rhodesia a fresh embargo was imposed by the Belgian Congo on all imports across its southern

frontier; this remained in force in 1936. An agreement was subsequently made between the Rhodesias and Bechuanaland by which imports of breeding stock were permitted, but slaughter cattle would only be imported under permit in cases of actual necessity; in 1935 the agreement was renewed for an indefinite period. This has had the effect of creating a protective market in the copperbelt for Northern Rhodesian cattle, and also of destroying the market for Bechuanaland cattle, which had been created by the restriction of movement of cattle from Barotseland owing to pleuropneumonia in 1914.

Local quarantine regulations prevent the marketing of native stock and where maintained in force over long periods contribute to overstocking. This has been particularly important in Kenya and in the Union. Where, however, it has been realized that it is imperative to encourage the disposal of surplus stock, measures such as the establishment of controlled routes for the movement of stock have been introduced as an alternative to the complete prohibition of such movements.

(c) Slaughter Cattle and the Meat Industry

With Africans the sale of cattle is either of secondary importance, or in some cases is rendered difficult by restrictions imposed through force of circumstances; again the breeding of cattle for meat is imperfectly understood, and the breeding of cattle for meat and the market is at present largely confined to the European community in South and East Africa. In the Union it is estimated that 600,000 cattle are slaughtered every year, of which some 90,000 are imported from neighbouring territories. Since 1924 restrictions requiring imported cattle to be over a fixed minimum weight have been imposed, and a subsidy scheme was inaugurated in 1932 in order to stimulate the export of chilled beef. It is said that grass-fed South African cattle are better suited to the chilling process than those from the alfalfa regions of the Argentine. The trade is further encouraged by bounties. In 1936 the total quantity of meat exported was 22,683,372 lb. Auction sales for native stock have been organized by the Veterinary Department in Natal and Zululand, and have begun to show some success in altering the attitude of natives towards their

cattle; some 10,000 cattle were sold in 1935-6.¹ South-West Africa exports considerable quantities of frozen beef from the Imperial Cold Storage Company's depot at Walvis Bay; the quality of stock is not suitable for chilling and freight charges are too high for the export of live cattle to be practicable.

Exports of slaughter stock from Bechuanaland have been severely restricted by quarantine regulations in neighbouring territories, and by the closing down of the Angola diamond mines, which up to 1925 provided a market for this territory. A cold-storage market opened in Durban in 1926 allowed a quota of 10,000 cattle to the protectorate, but prices were so low that the administration had to resort to export bounties in order to compete with Union cattle. The development of a chilled beef export depends on the possibility of organizing it in the months when supplies are relatively short in the United Kingdom market. The establishment of a canning and meat-extract factory has also been recommended.²

In Southern Rhodesia the local market is the principal outlet for cattle and absorbs about 80,000 head annually. The shipment of live cattle to England was attempted in 1926, but high freight charges made this unprofitable. In 1936, however, 1,660 cattle were exported to the Union. The chilled beef trade is now being developed through the agency of the Rhodesian Export and Cold Storage Company; and Messrs. Liebig's meat-products factory at West Nicholson absorbed 37,237 cattle in 1936. It must be realized that, though the existence of a factory is valuable, it gives an opening mainly for low-grade, not for quality cattle. In Northern Rhodesia cattle are slaughtered entirely for the local market, which, as has been mentioned, is protected by quarantine regulations.³ About 11,000 cattle were sold for slaughter by natives in 1936. The total absorbed by the market was between 16,000 and 17,000. It is predominantly a low-quality market.

Nyasaland has found an export market for cattle in the Lupa goldfields, to which 1,200 head were exported from North Nyasa in 1936. In that year the number of cattle slaughtered, about

¹ For native markets, see Chap. XX, p. 1421.

² *Report*, op. cit., Cmd. 4368, 1933, pp. 129-30.

³ See *Laws*, vol. iii, cap. 87, 1934.

2,000, represented a great increase on any previous year. In Tanganyika and Uganda the sale of cattle is increasing; local markets absorb practically all the animals sold. Here again there is a market only for low-quality cattle. In Kenya the organization of a meat-products factory as an outlet for surplus stock has repeatedly been urged,¹ and in 1937 one was opened by Messrs. Liebig in the Masai Reserve. Up to the year 1936, not more than 30,000 cattle and 66,000 sheep and goats were slaughtered annually. In 1936 Kenya and Uganda together exported 7,393 cattle and 8,897 sheep and goats.

In Nigeria meat is a regular article of native diet; in 1936 an ascertained total of 426,818 cattle were slaughtered during the year, and the actual total is believed to be much higher. Not all of these, however, were bred in the territory, as some 123,000 cattle entered from neighbouring French colonies during the year. In the Gold Coast, where there is also a large native consumption, an important problem is the prevention of the slaughter of immature animals. In both cases demand is only for the type required in a native market.

Pig products are of importance in a few territories only. Experimental shipments of frozen pork have been made from Southern Rhodesia, and in Kenya there is a bacon and ham factory which supplies local needs and in 1936 exported 1,168 cwt.

(d) *Hides and Skins*

In the Union of South Africa exports of hides and skins produced by European farmers are subsidized by government and were valued at £1,882,485 for 1936, over half being sheep skins; only wool and fruit exports exceeded this amount in value. From South-West Africa karakal pelts have been exported to the number of 814,561 in 1936. Hides and skins exported from Basutoland were valued at £2,526 in 1936, and from Bechuanaland at £23,777. In Bechuanaland native hides and skins were reported in 1933 to have become practically unsaleable owing to the unsatisfactory methods of preparation used and the difficulty of teaching new methods;² the preparation of karosses

¹ See, for example, *Report of the Agricultural Commission*, 1929, p. 30.

² *Report*, op. cit., Cmd. 4368, 1933, pp. 28-9.

has, however, been much improved in recent years as the result of official propaganda. Southern Rhodesia in 1937 exported over five million lb. of cattle hides. The hide industry is encouraged among natives by propaganda in methods of preparation. Small exports of ox hides, sheep and goat skins are made from Northern Rhodesia, and trade in hides from Nyasaland began in 1936 with an export of about 500 to Tanganyika.

In Tanganyika 3,094 tons of hides and skins mainly produced by natives were exported in 1936. The value of well-prepared hides is said to have been raised about 10 per cent. by propaganda on flaying and shade-drying; efforts are being made to develop the industry of sheep and goat skins by means of similar improvements in preparation. In Kenya the export in 1936 of 32,462 cwt. of hides represents a decrease on previous years owing to the reduced mortality from drought conditions in the native areas. Shade-drying has been actively encouraged by the provision of sheds for the purpose at all centres where cattle are slaughtered in considerable numbers, and rules making shade-drying compulsory have been imposed in some districts with the co-operation of the local native councils. Shade-drying, although difficult to supervise, is being adopted also for goat skins. In Uganda 20,943 cwt. of hides, of which 1,918 cwt. were shade-dried, were exported in 1936.

In Northern Nigeria a systematic campaign for the improvement of hides and skins has been undertaken through public instruction in flaying, which is given in over a thousand native authority markets. The most valuable skin produced in Nigeria is that of the red Sokoto goat, and the breeding of herds of pure red goats is being actively encouraged. In the recent period of high prices the slaughter of sheep and goats for their skins was carried to a point where the depletion of the herds was threatened, but a decrease in exports in 1936 is taken as an indication that the danger has been recognized. In this year exports were: cattle hides, 9,833,396 lb.; sheep skins, 1,376,961 lb.; goat skins, 4,585,751 lb. Exports from the Gold Coast were 8,589 cwt. of hides and 4,944 cwt. of skins. Hides and skins are also exported in small quantities from Sierra Leone and the Gambia.

French West Africa in 1936 exported 1,766 metric tons of hides and skins; the French Cameroons exported 508 metric tons of hides and skins. This industry is being developed in Equatorial Africa.

(e) Wool

Merino wool is the principal agricultural export of the Union; in 1936 the amount exported was about 214,000,000 lb. Native wool exported in 1935-6 amounted to about 47,000 lb. Exports of mohair in 1936 were 6,341,602 lb. The export of wool from South-West Africa, where the country is not suitable for merino sheep, is of minor importance. Wool is the most valuable animal product of Basutoland; its intrinsic quality is good, but marketing in poor condition has given it a bad reputation, and measures for grading have now been taken. The export in 1936 was 5,986,871 lb. and exports of mohair in the same year were 817,849 lb. In Southern Rhodesia and in Kenya wool is a product of European farming; the former country in 1936 exported 63,936 lb., principally to South Africa, and Kenya exported 1,458,912 lb. French West Africa exported 205 metric tons of wool in 1936.

Dairying

In most African territories the manufacture of ghee¹ has been the principal dairy industry developed among native stock-owners, but butter and cheese production have attained some importance in areas of European settlement. In the Union, dairying is organized under the Dairy Industry Control Board, which controls the erection of creameries and cheese factories and four condensed-milk factories. In 1936 there were 58 creameries, 109 cheese factories, and 4 condensed-milk factories. Eight native creameries are supervised by the Native Agricultural Department. Total production was 46,565,000 lb. of butter and 11,183,000 lb. of cheese. Exports were 11,186,000 lb. of butter and 2,459,000 lb. of cheese. Export bounties are paid, to which producers contribute by means of a levy. A state-aided scheme for the supply of milk and cheese to schools and of butter to charitable organizations,

¹ Clarified butter.

either free or at reduced prices, was inaugurated in 1935. In South-West Africa efforts are being made to expand the dairy industry by means of three large creameries, which have facilities for the renovation of tainted butter, but exports are at present small.

Cream is produced in the south-western part of Swaziland, which is within easy reach of the creamery at Piet Retief; natives participate in the industry where separators are available, but in the large central area production would not be practicable without the establishment of a local creamery.¹ In Bechuanaland there are now two creameries controlled for purposes of marketing by the Union Dairy Industry Control Board. Cream is produced by hand separator in native areas within thirty miles of the railway line, but the yield is low, and the quality inferior to that produced by Europeans. Butter cannot be profitably produced for export, but cheese is made as a home industry and exported to the mining areas in Northern Rhodesia and the Congo. The development of dairying without careful selection of cows which can give enough milk both for dairying and calf rearing may lead to the deterioration of herds, but in this territory, where various measures restrict the export of cattle, it appears to be an economic necessity.

In Southern Rhodesia eight registered creameries produce over a million pounds of butter annually, of which about a quarter is exported under a bounty system. The principal markets are Northern Rhodesia and the United Kingdom; there is also a large local consumption. Northern Rhodesia produced 206,052 lb. of butter in 1936. A co-operative creamery at Lusaka is supplied by seventy-eight producers. Native participation in the trade is negligible: one mission collects cream from them.

In Tanganyika ghee is prepared under the supervision of the veterinary department at centres in the Central and Western Provinces, which are opened temporarily during the period when there is a milk surplus. This measure is said to stimulate efforts by native herdmen to obtain the maximum quantity of milk. In 1936 there were ten factories in operation in the Central Province and three in the Western Province. In the Musoma area in the

¹ *Report on the Financial and Economic Situation of Swaziland*, Cmd. 3114, 1932, p. 140.

Lake Province the ghee industry is entirely privately managed and produced about 700 tons in 1936. A new method of production in which the cream is boiled direct to ghee without being churned was introduced during the year. Musoma ghee is exported to all parts of Tanganyika, to the neighbouring territories and the Arabian coast, and the limit of production has been reached.

In Kenya butter and cheese are produced in the European areas, and the export of butter in 1936 was 24,984 cwt. Ghee is produced in native reserves and the principal sources are in Central and South Kavirondo; in the purely pastoral areas with their low rainfall there is rarely a milk surplus, but encouragement is given to its production by means of dairy units established at suitable centres during the short periods of abundant rainfall when milk is plentiful. The dairy unit consists of a churn, separator, and accessory equipment, the capital expenditure for which is met by local native councils or occasionally by enterprising individual natives. The number of dairies is limited, and exports cannot be developed till a guarantee of standard quality can be given.

In Nigeria the commercial manufacture of ghee was first encouraged by the veterinary department in 1931 through the establishment of buying posts which supply central depots for dairying and packing. The United Africa Company now organizes this industry and has erected factories at Jos and Kano; the product is of a high quality and commands a ready market in the United Kingdom. In the Belgian Congo European farmers in 1936 produced 55,458 kilos of butter and 3,943 kilos of cheese.

V. AGRICULTURAL RESEARCH

Research work bearing on the problems of European and native agriculture is carried out by scientific bodies in Europe and South Africa, by the Agricultural Departments of the different territories, and to a certain extent by commercial organizations.

(a) *Institutions for Research in Great Britain*

In Great Britain the Royal Botanic Gardens at Kew and the British Museum of Natural History at South Kensington include

the study of tropical crop plants in the subjects of their research. The Imperial Mycological Institute for the study of plant-diseases is situated at Kew, and the Imperial Institute of Entomology, whose work on insect pests is relevant to the agricultural problems of Africa, is at the British Museum of Natural History. These two institutes, together with the eight Imperial Agricultural Bureaux which are located at research stations, co-ordinate information. The principal centre for general agricultural research in Britain is the Rothamsted Experimental Station at Harpenden, where the Soil Science Bureau is stationed. Soil science is studied here, at the Soil Laboratory at Oxford, and at the Macaulay Institute at Aberdeen. Work on plant genetics for crops other than herbage is done by the Plant Breeding Institute of the Cambridge School of Agriculture, where the Bureau of Plant Genetics (Crops) is situated; herbage plants are studied at the Welsh Plant Breeding Station at Aberystwyth, where the Bureau of Plant Genetics (Herbage) is situated. The East Malling Research Station in Kent, where the Fruit Production Bureau is stationed, is of much importance to Africa. The Low Temperature Research Station at Cambridge has made special studies in connexion with produce exported from Africa. The Institute of Agricultural Parasitology at St. Albans, where the Agricultural Parasitology Bureau is stationed, specializes in the study of plant pests. The work of the London School of Hygiene and Tropical Medicine is relevant to animal husbandry in so far as it deals with insects which attack stock as well as man. There is a veterinary research laboratory at Weybridge: the Bureau of Animal Health is stationed here. Animal nutrition is studied at the Rowett Research Institute at Aberdeen, where there is the Bureau of Animal Nutrition. Animal genetics are studied at the Institute of the University of Edinburgh, where the Animal Genetics Bureau is established. The Imperial Bureaux¹ publish abstracts of information, while the Imperial Institute publishes in its bulletin the results of research connected with the commercial development of agriculture. The centre for research and training in tropical agriculture for the British Empire is the Imperial College at Trinidad.

¹ See E. B. Worthington, *op. cit.*, chap. xi. See also Chap. XXIV, p. 1618.

(b) *Empire Cotton Growing Corporation*

The Empire Cotton Growing Corporation, which was established in 1921, maintains its own research stations in a number of British territories. The Corporation head-quarters for African research is at Barberton in the Transvaal, where the U₄ variety now grown over a very large area in southern and eastern Africa was first produced. From this station, where a staff of nine specialists is at work, the Corporation's research on insect pests throughout Africa is co-ordinated. In the Union they have a second station at Natal, with a staff of four, which carries out work under both rainfall and irrigation conditions. In Swaziland they maintain a station with one officer and an entomologist at Bremersdorp, with a sub-station in the low veld. In Southern Rhodesia the Gatooma station is maintained by government and staffed by the Corporation, and in Northern Rhodesia experimental work is carried out by an officer of the Corporation at Mazabuka. In Nyasaland they maintain a station at Domira Bay, with a staff of four officers who supply selected seed for the protectorate and have experimental plots in other areas. In Tanganyika they make a grant to the agricultural department for the maintenance of experimental stations at Morogoro, Kingolwira, Ukiriguru, Lubaga, Uzinza, and Mpanganya. In Uganda they contribute towards the maintenance of a cotton-seed farm, and have made grants for special post-graduate training to two members of the agricultural department. In West Africa they finance a seed farm at Daudawa in Nigeria.

(c) *Union of South Africa*

In South Africa the Faculty of Agriculture of the University of Stellenbosch was amalgamated in 1926 with the Elsenburg School of Agriculture to become the Stellenbosch-Elsenburg College of Agriculture. Pretoria University maintains a large agriculture experimental station, and the University of the Witwatersrand has since 1932 developed the Frankenwald Estate, acquired under the Beit bequest as a station for pasture research. Pretoria University gives a five-year course in veterinary science and a four-year course in agriculture. Of government organizations the veterinary

laboratories at Onderstepoort founded in 1902 carry out a comprehensive programme of research on stock diseases and in all aspects of animal industry. The work done on East Coast fever has already been mentioned, and work has been done on other tick-borne diseases.¹ A special laboratory for wool research was recently opened. The extensive study now in progress of the digestive system of ruminants is expected to have important results. Onderstepoort is now one of the best-equipped institutions of its kind in the world, and an especial feature of its work is the close touch maintained, through its field organization, with individual stock-breeders throughout the Union.

The Department of Agriculture has a number of sections devoted to research of different types; its main centre is at Pretoria. The economic research section has investigated costs of production of maize, butter and cheese, deciduous fruit, wool, and mohair. Soil research has included a general soil survey of the territory, and experiments with fertilizers and soil surveys for irrigation schemes. Grass and pasture research, which involves problems of the highest importance in the Union,² is being conducted over a wide range of country with varying soil and climatic conditions; there is a concentration on finger grasses, as being specially suited to most conditions. A field husbandry research section deals with the breeding of disease-resistant strains of maize, wheat, barley, and oats. At Rustenburg varieties of tobacco are under trial and experiments are made in connexion with flue-curing. A horticultural research section has also recently been created. Citrus investigations have been made at Nelspruit and Buffelspoort, and there is a special station for pineapples at Bathurst. Viticultural research is conducted at the Paarl station. The Low Temperature Research Laboratory at Capetown studies improvements in the methods of pre-cooling and storage of fruit for export. The African Explosives and Industries Company has carried out research on cereals and insecticides, and the Zebedelia Citrus Estate organizes its own research. The Sugar Association has a private experimental station at Mount Edgcumbe. At the Natal Sugar Experiment Station investigation is carried out on behalf of the sugar industry, and

¹ See E. B. Worthington, *op. cit.*, chap. xiv.

² See Chap. XVI, pp. 1079 ff.

recently improved varieties of cane¹ have been selected and are said to be likely to replace the uba cane on many estates. There is therefore a wide range of inquiry being undertaken in the Union, but there does not appear to be any definite policy exercised in directing or co-ordinating investigations. Partly for this reason, the results obtained (while including some of the greatest importance) are of unequal merit.

(d) *Southern Rhodesia*

In Southern Rhodesia the Veterinary Research Station near Salisbury, founded in 1916, has studied the control of foot and mouth disease by intramucosal injection, and has investigated East Coast fever, heart-water, and horse-sickness. Research on trypanosomiasis is carried out at the Hillside Station. Cattle-breeding research has included a study of the comparative results of grading up with introduced animals or breeding from the Afrikaner type. There is a separate dairy research institute.

An agricultural experiment station was founded at Salisbury in 1909, and now has two branches, Salisbury and Hillside. Pasture research is carried out at Salisbury and at stations established for the purpose in 1929 at Marandellas, Matopos, and Rusape, where local grasses are selected and bred for grazing yields. The Trelawney Tobacco Research Station, maintained by contributions from government and the tobacco industry in equal amounts,² has done valuable work on nematode pests. The Tobacco Research Board prepares programmes of research work and controls a trust fund consisting of contributions from firms and individual growers.

A citrus research station at Mazoe is financed by the British South Africa Company.

(e) *British Colonial Areas*

Agricultural and veterinary laboratories were opened at Mazabuka in Northern Rhodesia in 1929. A veterinary section main-

¹ The best of these canes are said to be POJ 2725 and POJ 2878 from Java, and CO 290 from India. From 1927 to 1930 the cultivation of varieties other than uba was prohibited, except in quarantine, the aim being the eradication of mosaic disease. Since 1931 other varieties, including some already mentioned, have been released for general planting; they have been found generally resistant both to mosaic and streak disease.

² See the Tobacco Research Act, 24 of 1935.

tains pedigree and common breeds of cattle and sheep, chiefly blackhead Persians, for breeding research. Stations at Abercorn and Fort Jameson specialize in coffee and tobacco respectively, and a station to be devoted to problems of native agriculture was opened at Lunzua in 1935. In Nyasaland the head-quarters of research are at Zomba, and subsidiary stations are maintained at Port Herald, Makwapala, Lilongwe, and North Nyasa. The station at Mlanje is devoted entirely to tea research and has recently given special attention to the problem of poor fermentation of leaf grown in certain soils in the high rainfall belt.

The head-quarters of 'long-term' agricultural research for East Africa are at Amani, in Tanganyika, a station established in 1902 by the German administration.¹ The Agricultural Department for the territory has its head-quarters at Morogoro; for *arabica* coffee a research station was opened in 1933 at Lyamungu, with the assistance of a grant of £23,000 from the Colonial Development Fund to meet recurrent expenditure for the first five years. This station serves all East African territories, dealing mainly with cultivation methods; it has also studied the antestia pest and armillaria root disease. *Robusta* selection is done locally; for Tanganyika this is carried out by the Amani Station, and field experiments are made at the coffee training-centre at Nyakato, in Bukoba district. The Veterinary Department has a laboratory and experimental farm at Mpwapwa. The existence of a special Tsetse Research Department, which works in co-operation with the Health, Agricultural, and Veterinary Departments, is a unique feature of this territory.² Sisal growers have contributed funds for the establishment of an experimental station at Mlingano, near Tanga, which maintains co-operation with Amani. In addition, Tanganyika and Kenya sisal producers jointly have financed a scheme of consumption research which is being carried out from the linen industry research station at Lambeg in Ireland. The experimental work at Mlingano includes comparisons between the green and blue sisals, of which the latter (*Agave amaniensis*) shows great promise. An important result has been the greater measure of growth known to be attained by sisal kept free of weeds, as compared with that grown under other conditions.

¹ See below, p. 955.

² See Chap. XVII, p. 1132.

In Kenya the main centre for agricultural research is the Scott Agricultural Laboratory at Kabete,¹ which was first started as an experimental farm in 1907. There is a separate plant-breeding station at Njoro. Coffee has been the subject of much research which has included the control of pests, particularly mealy bug and *Antestia lineaticollis*; the latter appears to be capable of control by the use of finely ground pyrethrum, which is locally grown.

On the recommendation of Sir Alan Pim, a team of agricultural officers was appointed in 1937 to work on coffee research in co-operation with the research workers at Amani and Lyamungu in Tanganyika.²

The types of wheat now grown in Kenya have been evolved at the plant-breeding station, with the co-operation of plant pathologists in the study of rust diseases. Varieties of cotton are being tested at the Kibirani experimental station, and experiments are being made with Madagascar butter beans for strains resistant to 'yellow eye'; varieties are also sought which will be resistant to the bacterial blight, prevalent in wet conditions above 7,000 feet. An awned bulrush millet which is bird-proof has been introduced from Tanganyika as an improvement on local varieties.

Veterinary research, in addition to the study of rinderpest already mentioned,³ has also been concerned with tsetse research, the last in co-operation with the Tanganyika Tsetse Research Department. A government stock farm was opened at Naivasha in 1935 for work upon nutritional and genetic problems, particularly in connexion with mineral deficiencies in the pastures.⁴ Breeding experiments are carried out by means of artificial insemination.

Uganda has an agricultural laboratory at Kampala with four subsidiary experiment stations. A cotton experimental station was opened at Kadunguru in 1911, and there are now two selection stations; local study of the blackarm disease of cotton has had valuable results. A veterinary laboratory at Old Entebbe has made a special study of tuberculosis and East Coast fever, of which local workers believe Uganda to be the home. A special sub-laboratory was opened in 1932 for the manufacture of serum; this

¹ See below, p. 972.

² *Report on the Financial Position and System of Taxation in Kenya*, Colonial 116, 1936, p. 141.

³ See above, p. 934.

⁴ See Chap. XXIV, p. 1618.

would seem to present disadvantages in view of the small staff available and the fact that provision is also made in Kenya. There is no entomologist attached to the Veterinary Department, but it is held that field studies have produced knowledge of fly and tick areas sufficient for practical purposes. Stock farms are maintained at Koja, Sukulu, and Soroti, and native administrations maintain farms under the supervision of the Veterinary Department at Boroboro and Mbarara.

Bananas have been studied in Uganda, particularly with a view to control of the banana weevil by a predator introduced from Java. Coffee seedlings are reared from selected seed and are distributed by the Department of Agriculture. Wild varieties are being collected for breeding purposes, and good results are expected from a type found in the Imatong mountains in the southern Sudan, where conditions resemble those in the drier parts of Uganda.

Nigeria has research laboratories at Ibadan for the Southern and at Samaru for the Northern Provinces. In respect of soil investigations, the work done on the poor soils of the South-Eastern Provinces, known generally as Benin sands, may be mentioned; one result of this has shown that on the Owerri soils, which are deficient in phosphorus, the direct application of ground rock phosphate to a grain crop was less effective than the application to *Mucuna* beans used as a green manure.¹ Entomological work has included a study of the breeding-grounds of locusts, undertaken in collaboration with French authorities, and research on cotton stainers, yam beetles, the *Sahlbergella* bug of cacao, and the disease vectors of cassava mosaic and tobacco leaf-curl. The stock farm at Shika has paid special attention to the breeding of cattle for mixed farming. In the Northern Provinces selected cotton seed is distributed from the Empire Cotton Growing Corporation farm at Daudawa. In the Southern Provinces the problem has been to replace imported American cottons, which were found unsuitable, by an improved native variety; the improved Ishan type was first distributed in 1927 and is now in general use. Experiments in the crossing of Ishan with Sea Island cotton are being made in collaboration with the Empire Cotton Growing

¹ See below, p. 962.

Corporation's research station at St. Vincent.¹ Cacao research began at the Moor Plantation in 1930, and is carried on in collaboration with the Imperial College of Tropical Agriculture in Trinidad. The Ibadan native authority finances a special selection farm. The selection of cowpeas resistant to nematode attack has been begun in Nigeria, and trials are being made at Moor Plantation with *robusta* coffee seed introduced from Java, and with citrus fruits.

Oil-palm selection was started at Calabar in 1927, and additional experiment stations established since that date now extend over 77 acres. High-yielding varieties have been selected.

In the Gold Coast the central agricultural laboratories are at Accra, and there are experimental stations at Tamale, Asuansi, Kumasi, and Kpeve in Togoland. The Tamale station has carried out cultivation and manure trials with yams, cassava, ground-nuts, rice, and grasses. Asuansi has specialized in citrus and bananas. Kpeve studies crops typical of the forest and savannah belts; Kumasi is a centre for botanical work on cassava breeding and selection, but is mainly organized as a demonstration station for the training of agricultural students.² Recent entomological work has included study of the cacao moth and the fruit-piercing moth which attacks citrus; soil surveys with special reference to cacao have been carried out in co-operation with cacao research in Trinidad. An advantage of the new experiment station at Tafo is that it is nearer to the laboratory head-quarters than the older experiment stations. The research staff consists of an entomologist, a botanist, a chemist, and a plant pathologist. Valuable veterinary research work is carried out at Pong-Tamale.

In Sierra Leone the laboratories are at Njala. Research into oil palms is carried on at the Masanki plantation; the conclusion reached is that the imported varieties are superior. Experiments are made in breeding Deli palms and Angola palms from the Congo. Rices for cultivation on naturally flooded lands are tested at Scarcies in Sierra Leone, where varieties from India, Ceylon, British Guiana, and Indo-China have been introduced, and pure-line strains are selected from local varieties. At Njala similar work is done for inland swamp and hill rices.

¹ See above, p. 945.

² See below, p. 968.

(f) *Other Territories*

In France the *Musée National d'Histoire Naturelle* has a section devoted to colonial plants and tropical agriculture, and the *Institut National d'Agronomie Coloniale*, which was founded for the training of colonial agricultural officers, is expected to develop eventually as a centre for research. Both institutions are situated in Paris.

In French territories 'long-term' research is for the most part organized by visits of specialists from institutions in France, and the research work done by the colonial personnel consists mainly in plant and animal breeding.

The most important centre for agricultural research in French West Africa is that maintained by the Niger Office at Ségou in connexion with its irrigation schemes; the staff includes agricultural chemists, an entomologist, and also plant breeders and plant pathologists. There are also agricultural stations at M'Bambey in Senegal, Kindia and Kankan in Guinea, La Mé, Bingerville, and Gagnoa in the Ivory Coast, and Pobé, Niaouli, and Ina in Dahomey. The principal animal-husbandry station is at Sotubà in the Sudan; in this colony there are also three minor stations for merino, karakal sheep, and goats, at El-Ouladji, Nioro, and Nara. In the Ivory Coast there are stations at Bouaké and Koroko; in Dahomey the Ina station has a veterinary branch and Mauretania has an experimental sheep farm at Maderdra. The headquarters of research on animal diseases is at Bamako in the Sudan, which co-operates with the Pasteur Institute laboratory at Kindia. Cacao is studied at Bingerville and Gagnoa, banana cultivation at Gagnoa, rice selection at Kankan, selection for groundnuts at most stations, and oil-palm selection at La Mé and Pobe. M'Bambey is a centre for research on groundnuts.¹

French Equatorial Africa has four cotton-selection stations and a small coffee experimental station. In the Cameroons cacao and *robusta* coffee selection work is done at Ebolowa, and a station at Dschang specializes in *arabica* coffee and in experiments with

¹ M. Sagout, 'Exposés des travaux de sélection généalogiques de l'arachide et des résultats obtenus à la station expérimentale de M'Bambey', *Bulletin mensuel de l'Agence économique de l'A.O.F.*, 1937, pp. 351-4.

introduced plants. At Dschang there is also an experimental farm which concentrates on the breeding of small stock and poultry.

In Belgium the State Botanical Garden at Brussels has a large collection of tropical plants; the Botanical Department of the *Musée du Congo Belge* at Tervueren was merged with it in 1934. The University of Louvain has devoted much attention to the study of colonial agricultural problems. It has an institute for research in soil science, and since 1931 has organized its own research centres in the colony for the purpose of improving native agricultural methods, with special reference to the cultivation of food crops; the organization is known as the *Cadulac* (*Centres Agronomiques de l'Université de Louvain au Congo*). In the Belgian Congo both agricultural and veterinary research is carried out by the *Institut National pour l'Étude Agronomique du Congo Belge* (*Inéac*) established in 1933. The principal experimental stations of the *Inéac* are Yangambi, where cultural methods for rubber, oil palms, coffee, and native food crops are studied; Gazi, where the work is concentrated on rubber and cacao; Lula, in connexion with *robusta* coffee; and Bacumba, which has given special attention to the regeneration of exhausted soils and has plantations of oil palms and cacao. Cotton stations at Bambesa and Gandajika study the control of pests in addition to selection work: only seed approved by *Inéac* is distributed to native cultivators. The principal work of the stock farm at Nioka, near Lake Albert, is the improvement of native cattle in connexion with mixed farming; it also carries out research on food crops and coffee.¹

In Portuguese East Africa a central laboratory for veterinary pathology at Lourenço-Marques is conducted in connexion with an experimental farm and a number of subsidiary farms in the principal cattle areas. Angola has a veterinary laboratory in the highlands and stock farms in the Ganda, Humpata, Cuanhama, and Quilengues districts. With the exception of Humpata, which specializes in the production of wool, milk, and working beasts, these are mainly devoted to the breeding of cattle and sheep for export.

¹ See E. B. Worthington, *op. cit.*, chap. xi.

(g) Ecological Surveys

A special type of field research that has been developed in some British territories, particularly in Northern Rhodesia, is the agricultural or ecological survey. In Uganda the so-called *mutala*¹ surveys are organized by a committee appointed in 1935. Each survey consists of a close examination of the social life and agricultural activities of the people concerned; the study of nutrition has recently been added. Nineteen surveys have been instituted, largely to provide a basis for the redistribution of population from areas where soil fertility is becoming exhausted; as in all inquiries of this nature, carried out by a number of officers of different training and experience, the results are unequal, though they contain much useful information. An ecological survey of a different class is being carried out in Northern Rhodesia by an ecologist and an agricultural officer. Work has been completed in the north-western part of the territory² and is continuing in the eastern areas; it consists of an intensive examination of soil conditions, water supplies, population density, existing systems of agriculture, and the possibilities of the development of cash crops.

(h) The Co-ordination of Research³

In the circumstances of Africa, the term 'research' has, as is noted in dealing with the problems of health, acquired a much wider meaning than would be usual in Europe. The institutions for research to which reference is made in the preceding sections belong to a variety of classes. At the top of the scale there are institutions where an adequate team of workers, free from routine work, are able to devote themselves to the investigation of problems requiring a detached study; at the other end, there are cases where a small staff is faced with a great mass of routine work, much of which would in Europe devolve on qualified assistants, and can spare but little time to deal with the more urgent of the local problems requiring investigation. In the British territories it has been customary for each administration to appoint specialist

¹ *Mutala* is the vernacular name for the hill slopes divided by swampy valleys on which the villages and gardens stand.

² C. G. Trapnell and J. N. Clothier, *op. cit.*

³ See Chap. XXIV, *passim*.

officers to its staff, sometimes on the general principle that the problems of the territory need separate study, sometimes in reply to a definite demand from those, such as the growers of sisal or coffee, or the exporters of palm oil, whose output has suffered from crop disease, or who have desired to improve the quality of their production. In principle, the general co-ordination of agricultural policy, including the direction of specialist inquiries, is sought through the Colonial Advisory Council of Agriculture and Animal Health, acting partly on the annual reports issued by the Agricultural Department in each territory, partly on the results of the periodical visits to Africa of the Agricultural Adviser to the Secretary of State. Valuable as are these visits and the recommendations made by the Advisory Council, they do not constitute a co-ordination of research policy, in the sense in which the word would ordinarily be used. To a certain extent the inquiries made by specialist officers are dictated by circumstances, such as the marked prevalence of a pest or disease, or a request made by the interests which have influenced the creation of the specialist post; but for the rest there is no system in force by which, for example, problems awaiting inquiry can be distributed over the staff of the different territories concerned, or the preparation of sera or vaccines required by the animal-health staff can be centralized. Making full allowance for the fact that the personal interest or experience of the worker is a factor of primary importance in the success of any form of scientific inquiry, the failure to establish any system for the co-ordination of work of this class is nevertheless unfortunate; that in some cases it leads to overlapping of effort is obvious, while in others inquiry is undertaken which should clearly be left to those who are better situated in regard to both experience and equipment. It is difficult to believe that under this system it is possible to make the best use of the small resources available for research into the problems of agriculture and animal husbandry.¹

For the East African territories some attempt was made to systematize agricultural research through the Amani Station, which was constituted as a centre of research for Kenya, Uganda, Tanganyika, and Zanzibar in 1925. Its scientific staff consists of the

¹ See Chap. XXIV, p. 1632.

director, a plant pathologist, an entomologist, a soil chemist, a bio-chemist, a plant physiologist, a plant geneticist, and a botanist. The aim of the centre is to study problems requiring more prolonged research work than can normally be expected from the technical staff of any single administrative department, and problems arising in more than one territory towards the solution of which the comparative method may be expected to make an effective contribution.¹ The Institute has, however, no control over the work done in other centres and it does not act as a co-ordinating body. It has at the same time a useful function as a centre of information and advice; members of its staff are available to undertake work in the different territories which cannot be done by local officers, and provision can be made for local officers to visit Amani for work on long-range problems such as soil studies. It is of some interest to note the nature of the work done by the Station within the specific field allotted to its own activities. In co-operation with agricultural chemists in various territories, a provisional soil map of East Africa has been compiled on the basis of material supplied at two inter-territorial conferences of agricultural chemists. A special study has been made of the ecology of the antestia pest of coffee, and work has been done in connexion with the mosaic pest of cassava, and locust research. Work on essential oil-yielding plants has received considerable attention, and in studying the physiology of coffee in relation to environment, important results bearing on the influences of shade on the physiological processes of the *arabica* coffee bush have been obtained. Extensive study of the rooting habits of coffee has yielded much valuable information, in particular as to the class of soil best suited for plantations. Sisal physiology has been included in the programme of research. In recent years 'physiological ecology', or the study of the plant's physiological functions in the field, has been considerably developed; it has, for example, been discovered that 'yellows' in tea can be prevented by applications of sulphur. Genetic studies have been made on coffee and sisal, and some research has been done on cinchona cultivation.

Much of the inquiry undertaken is, therefore, of the detached or (to use the term frequently employed in this connexion) 'long-

¹ Imperial Agricultural Research Conference, 1927, *Report*.

range' character. But it is seldom possible to establish on *a priori* grounds any clear-cut line between long-range and short-range inquiry, and the Station has, as already shown, also undertaken a range of inquiry into the planting problems of coffee, carried out in association with Lyamungu, or again into the cultivation of *Derris* and *Mundulea* (with a view to establishing them as local crops), which does not fall into the category of long-range work.

Conferences of directors of agriculture and research workers from all the East African territories, including Nyasaland and Northern Rhodesia, have been held in 1931, 1933, and 1936. Periodic joint conferences of medical and veterinary research workers in East Africa have been held at various centres, and at one time a proposal was made to develop the Kabete laboratories in Kenya as a central veterinary research institution for East Africa. It was contended that centralized research was more definitely required in connexion with animal diseases than in connexion with agricultural problems, since local variations between the different territories are less significant.¹

The isolation of Agricultural Departments in West Africa was the subject of comment by Sir Frank Stockdale, the Agricultural Adviser to the Colonial Office, after his tour of inspection in 1935-6;² he urged that opportunities should be afforded by the various administrations for exchange visits and the holding of conferences at which common problems could be discussed. Two such conferences had previously been held, in Nigeria in 1927 and the Gold Coast in 1929, but the practice had been discontinued on grounds of economy. Exchange visits are represented so far by the visit of an agriculturist to Nigeria from Sierra Leone in connexion with swamp-rice cultivation and from the Gold Coast in connexion with the study of mixed farming. It is suggested that exchanges might be arranged between all three territories, of persons engaged in fruit investigations.

Sources of information on the work done in each British territory are the annual reports of the Agricultural and Veterinary Departments and the periodical bulletins of a more or less popular nature which are issued for the guidance of local farmers, European and

¹ See Chap. XXIV, p. 1632.

² *Report*, op. cit., C.A.C. 270, 1936, p. 7.

native. A common arrangement for annual departmental reports was introduced by the Agricultural Adviser to the Secretary of State in 1936, but they contain in some cases material which is of no general interest. Sufficient attention is not paid to the need to distinguish between matters of strictly departmental interest (which need not necessarily be published) and those which are of public interest or permanent value. In the Union the Department of Agriculture issues a monthly publication, *Farming in South Africa*, and the Southern Rhodesia Department publishes a monthly agricultural journal. The *East African Agricultural Journal*, edited by the director of Amani and first published in 1935, contains articles on agricultural subjects contributed by members of all the East African Departments; more technical publications are the Amani memoirs, in which the results of specific investigations are published.

For West Africa there are fewer sources of information. The Nigerian Department began the publication of an annual bulletin in 1922, but this was discontinued during the economic depression, as was a similar publication, the *Gold Coast Year-Book of Agriculture*. Sir Frank Stockdale has recommended the re-issue of the former on the ground that the exchange of information on problems common to the West African territories is highly desirable.¹ A monthly publication, *The Gold Coast Farmer*, is issued by the Department of Agriculture.

The system followed in the French territories, by which research is under the direction of scientific institutions in Paris, and the work of local officers is largely confined to field inquiries,² makes for closer co-ordination of effort than in British territories, and for some considerable economy in staff; though it leaves less scope for individual initiative, and also perhaps takes less account of the variety of needs arising from local circumstances. No departmental reports are published, but some general information on agricultural subjects is given in the general reports issued annually from each of the mandated territories. The annual report of the Belgian Congo, and that of the mandated territory of Ruanda-Urundi, also give some general information, but no annual departmental reports are published for the Belgian areas.

¹ *Report*, op. cit., C.A.C. 270, 1936, p. 8.

² See above, p. 952.

(i) *Statistics*

In the main the statistics of cultivation and production in Africa are only estimates based on material of very varying value. Lands held by Europeans have for the most part been surveyed, so far at least as is needed to establish their boundaries and area; but with the exception of the relatively small areas held by natives in individual right in South Africa or Southern Rhodesia, or the native *immatriculé* areas¹ in French colonies, or the lands measured by a native administration survey, as in Kano,² lands in native occupation have not been cadastrally surveyed. The market figures give a sufficiently accurate basis for calculating the total annual output of certain types of crops grown mainly for export; but these figures cannot be related to the acreage under cultivation. Nor is it at present possible to calculate accurately the output per acre of different types of native crops; experience shows that, even where a cadastral survey exists, estimates of output based on the results of experiments at state farms or institutions need to be checked by measurements of output on surveyed areas of considerable size, cultivated under normal conditions. The measurements of output which are made annually over the large areas of controlled cultivation on the Gezira canal in the Anglo-Egyptian Sudan³ constitute a good example of such a check. Accurate statistics of native production cannot be obtained until some kind of cadastral survey has been made, and some systematized method of observing and recording output has been introduced. The making of a cadastral survey has, however, usually been necessitated as the result of a system of taxation which bases revenue on the land, or has followed the evolution of a system of individual rights, to which economic circumstances give a transferable value. It is not likely that circumstances will in any near future necessitate the making of a survey on any large scale, and thus prepare the way for the institution of a satisfactory system of statistics of cultivation and cropping.⁴ Meanwhile it may be advisable for British administrations to consider whether they will in the future adopt the decimal

¹ See Chap. XII, pp. 354 ff.

² See Chap. IX, p. 427.

³ See Chap. XV, pp. 1953-5.

⁴ For the question of the survey of land, and the record of rights, see Chap. XII, pp. 376-8.

system or the British system for the purpose of land measurements. British African dependencies already suffer from the infliction of the British system of weights; it would be unfortunate if in addition they had to bear for all time the eccentricities of the British system of surface measurement.

VI. THE IMPROVEMENT OF NATIVE AGRICULTURE

It is clear that the most urgent problem in all territories is the introduction of methods which will maintain soil fertility without extensive recourse to shifting cultivation.¹ But if new methods of fertilization are to win their way, they must be adapted to the financial and labour resources of the average native farmer, and it would seem therefore that they must be based on natural processes rather than on the use of artificial fertilizers. An examination of the present methods used by natives to produce food or cash crops will reveal a planned effort, the balance of which may easily be upset by ill-considered innovations. Cotton production in Southern Nigeria, for example, is combined with the cultivation of yams, maize, and beans, and the crops are planted at varying times and are not necessarily harvested in the order in which they were planted; hence the variation in the times of maturity allows a suitable distribution of labour, the soil is generally well covered, weeded, and cultivated, and full use is taken of the available soil fertility; it is also said that the possibility of crop failure through insect attack is diminished. Such a system is of proved value in native eyes and is peculiarly adapted to native conditions of life; it needs careful study before improvements can be recommended which are not only sound in themselves but will appeal to the cultivators.

Methods of improvement in regard to shifting cultivation which have suggested themselves as suitable to native resources are:—green manuring, which was first studied in Nigeria and is now extensively used in that territory; the more scientific rotation of crops, based on careful studies of the present native system; and composting, which has been regarded as better adapted to native methods than green manuring.² Another important step

¹ See above, p. 879.

² Sir A. D. Hall, *The Improvement of Native Agriculture in relation to Population and Public Health*, 1936, pp. 34, 38.

in the improvement of agricultural methods is the development of mixed farming, such as is already practised in some parts of Nigeria.

Again, it is clear that much can be done to improve types of seed. The usual practice in the case of cash crops is for seed to be set aside for use without any special method of collection. Seed farms are maintained in most territories in connexion with export crops, and in some cases they are run by the native authorities, but it is clear that if a continuous supply of planting material is to be maintained, considerable extension of this method of supply is necessary. There is need for agricultural education, not only by the provision of holdings where methods can be tried out under supervision, but also by the training of African staff to assist in the Agricultural Departments, to be demonstrators in the native areas and advisers to the native authorities. It will be necessary to give a concise account of these measures, and also to describe the problem of the control of plant pests and diseases.

The improvement of cash crops is important, but the primary aim among a people who are almost entirely dependent on their individual agricultural efforts for their food must be the improvement of subsistence crops in such a way as to maintain or increase production in spite of the difficulties involved by the changing conditions.¹ Malnutrition, which is widespread among African peoples, results, as has been remarked elsewhere,² in low resistance to disease, and French authorities have gone so far as to assert that shortage of food is the most serious obstacle to the increase of population. In some territories there is evidence that the cultivation of commercial crops has already led to the neglect of food crops; and both in the Gold Coast cacao regions and the Bukoba coffee area of Tanganyika, farmers are beginning to depend on bought food. Scientifically based measures for improvement of native diet await the results of research into the problems of native nutrition; in the meantime, however, agricultural research can be directed towards improvements in the yield of crops grown by natives, and towards popularizing introduced food plants.

¹ See above, p. 884.

² See Chap. XVII, pp. 1122-4.

(a) Methods of improving Soil Fertility

Green manuring, the digging in of green-stuff as soon as the land goes out of cultivation, is perhaps better adapted to plantation cultivation and settler farming than to native plots. In Southern Nigeria, however, green manuring with *Mucuna* (the Bengal Bean) has been found effective, nor is the practice alien to native systems, as the digging in of weeds is a common practice. *Mucuna* has the disadvantage in native eyes that it may occupy the land during a full season to the exclusion of a food or cash crop, and the increased yield in the following season is not recognized as compensation for this. It seems that investigation must be directed to the production of a green manure which will also thrive as a food crop. In East Africa conditions are often too dry for the use of green manures, and in Uganda permanent cover crops were found to reduce the yield of coffee. In the irrigated areas of the French Sudan it is believed that green manuring will make fallowing unnecessary. On this point, however, further experience is clearly necessary, especially in view of the history of cotton growing on irrigated lands in the Anglo-Egyptian Sudan.¹

Experiments in crop rotations have been made in Nyasaland and Northern Rhodesia, and in the latter a system incorporating maize, cotton, groundnuts, and beans is being developed. In Uganda trials in the rotation of elephant grass with cotton and food crops are in progress at Bukalasa, where land left under the grass for three years has been proved to regain its fertility; the roots act as a soil condition improver, and the luxuriant top growth provides material for mulching. Cassava has also been found useful as a rotation crop, and in Nigeria a rotation of yams, cotton, groundnuts, and maize has been found suitable.

A method of composting, in which vegetable waste and animal manure are kept in pits and turned and watered at regular intervals until fermentation is completed, has been suggested as suitable in native conditions.² In Nigeria trials in a mixed farming area gave results less satisfactory than those obtained with animal

¹ See Chap. XV, pp. 1053-5.

² See Sir A. D. Hall, *op. cit.*, pp. 34-8, and Sir A. Howard and Y. D. Wad, *The Waste Products of Agriculture*, 1931.

manure. In Kenya, however, compost, which does not involve a drain on soil moisture, was found preferable to green manuring in the drier maize-growing areas, and a factory was started in Nairobi in 1934-5 for the manufacture of compost from refuse such as bone residues, animal manure, cotton seed, and wood and tanning waste. African cultivators have not, however, readily adopted composting owing to the additional labour involved in the collection of waste products and the regular routine of watering and turning. In Uganda composting is an alternative use of cotton seed, which is at present exported, but lack of water makes it difficult in the dry season. In Tanganyika and Nyasaland experiments are also being made with composting.

The development of mixed farming, which many believe can alone make permanent cultivation possible, is limited in large areas owing to tsetse-fly. It received its first impetus from experience in Northern Nigeria, where the marked effect of even a small application of animal manure was observed in areas which are too dry for green manuring to be possible. After suitable cattle had been bred, housed, and trained to farm work, and appropriate fodder crops found for them, mixed farming was introduced on holdings set aside on government farms. Three farmers took up holdings in 1928; in 1936 the number was 1,053 and it is hoped that in five years it will reach 10,000, the system having been widely adopted on private holdings. It has been demonstrated that with a pair of working bullocks one man can cultivate 8 to 15 acres as against three by the hoe.¹ Native administration demonstration farms help to popularize the system, and the native treasuries make advances for the purchase of stock and implements, which are repaid over a period of four years; the transference of this enterprise to a co-operative society is under consideration. Limitation of the size of holdings to an area which can be efficiently worked is recommended by Sir Frank Stockdale.² The test of the method must be its ability to survive periods of serious drought. The Gold Coast Northern Territories have decided to develop mixed farming on Nigerian lines. Its extension to the tsetse belt of Nigeria depends upon the introduction of cattle tolerant of the

¹ See O. T. Faulkner and J. R. Mackie, *op. cit.*, p. 66.

² *Report*, *op. cit.*, C.A.C. 270, 1936, p. 28.

local trypanosome, for the Nigerian dwarf cattle are useless for draught purposes; herds imported from the Gold Coast Northern Territories have given promising results. A further study of the possibilities of introducing resistant types of cattle on a reasonably large scale is held to be necessary. The class of cultivation found in Northern Nigeria, and the fact that the native administrations there had sufficient resources to stimulate the practice of mixed farming, created circumstances unusually favourable to its introduction. There are strong arguments in favour of its introduction in other areas where physical circumstances permit it; but in the absence of equally favourable conditions, it is not reasonable to expect that it will have so general or so rapid an expansion.

(b) Agricultural Education

In dealing with certain of the other technical departments, such as those of Health and Forestry, occasion has been taken to remark that expansion in the activity of the department must depend largely on the training of African assistants qualified to undertake posts of responsibility.¹ In the British territories it is not unusual to find fully trained European officers of the Departments of Agriculture and Animal Husbandry discharging duties which would elsewhere be entrusted to trained assistants; instances are seen not only in operations of a partially administrative nature, such as the supervision of the marketing of cotton, or the charge of experimental farms, but in laboratory work, as, for instance, the preparation of vaccines or sera. This observation does not apply with equal force to the French territories, where the less technical work of the departments is often discharged by members of the general administrative staff, and some of the purely technical work is carried out by European subordinates. The same is true of the Belgian territories. So far, no systematic steps have been taken in British territories to train Africans as fully qualified assistants in the agricultural or veterinary services; but the development at Makerere of advanced courses of training in agricultural and veterinary science for students from all East African territories was one of the recommendations of the

¹ See Chap. XIV, p. 1020, and Chap. XVII, p. 1182.

1937 Commission on Higher Education in East Africa.¹ The inadequacy of the provision made for training assistants in West Africa has been the subject of comment by Sir Frank Stockdale, who in 1936 recommended the formation of a joint policy by the Directors of Education and Agriculture of the four West African territories.²

On the other hand, there exists in most territories some provision for training subordinates of a lower rank. A number of details will be found in the section of the chapter on education which deals with vocational training; some further details are added here. In the Union of South Africa officially organized agricultural education of Africans began with the creation in 1929 of the separate agriculture section of the Native Affairs Department. The four schools of agriculture³ have stock farms, but leave seed selection to the central research stations, a policy which seems to allow insufficient experiment for reaction to local conditions. Selected students work as demonstrators on plots of about 2 acres, using implements supplied by the Department of Native Affairs, or, in the case of the Transkei, by the United Transkeian Territories General Council. Improved seed and fertilizers are introduced in the second year of demonstration. Assistance is given in the castration and culling of stock and the introduction of better sires, and a demonstration caravan tours the territories every year. The Director of Agriculture estimated in 1932 that a minimum of 400 demonstrators would be necessary to make any real impression, and the Native Economic Commission regarded this as a conservative estimate;⁴ in 1936 the number employed was 152. The Interdepartmental Committee on Education of 1935 recommended that demonstrators should also advise primary teachers in connexion with their work in school gardens, and that a specialized teacher of agriculture should be appointed to the staff of every training school.⁵ The possibilities of improvement, however, are limited by the fact that many natives do not possess draught animals and cannot afford to buy implements, and by the absence of a great number from home at times when their gardens

¹ Colonial 142, 1937, pp. 93-5, 101-4.

² *Report*, op. cit., C.A.C. 270, 1936, p. 6.

³ See Chap. XVIII, p. 1222, and Chap. IX, p. 355.

⁴ *Report*, U.G. 22, 1932, paras. 100-2.

⁵ *Report*, U.G. 29, 1936, paras. 564, 572.

require attention. It has been suggested that these difficulties would be overcome by the introduction of collective farming by organized groups, who would pool labour and implements and undertake to carry out the necessary seasonal operations at the proper time.¹ It is estimated that this would effect a reduction of 50-75 per cent. in the labour units required, but it is not clear how such groups are to be organized. The Transkeian Territories General Council issues an agricultural journal in English and Xhosa, which is edited by the Director of Agriculture and has over 3,000 subscribers.

Demonstrators, trained in the Union, are employed in Basutoland and Swaziland, but not in Bechuanaland, where agricultural questions are less important than pastoral.

The organization of native education in Southern Rhodesia as an integral part of schemes for native development is mentioned elsewhere.² Here control is exercised over methods of cultivation on land allocated on individual tenure in the native purchase area. Demonstrators are trained at Domboshawa.³ In Northern Rhodesia it is held that propaganda should be delayed until more knowledge is available as to the value of native systems, and specially trained demonstrators are not employed. In Nyasaland native demonstrators acquire their knowledge while working for the Agricultural Department, special courses of instruction being arranged as opportunity offers.

Tanganyika employs a considerable African personnel trained in the Union; the instructors attached to the native authority farms have no special training other than the agricultural course in central schools. The training in coffee growing given at the Nyakato school⁴ is intended as a preparation for farmers rather than as a training for employment under the department; some pupils, however, are employed as instructors. Ploughing schools are maintained at Itheme and Lubaga.

In Kenya a separate staff for the development of native agriculture was first created in 1923, and the work done consisted in direct instruction of native cultivators and the maintenance of

¹ Department of Native Affairs, *Annual Report*, 1935-6, p. 38.

² See Chap. XVIII, pp. 1226-9.

⁴ See above, p. 948.

³ *Ibid.*, p. 1229.

small demonstration plots. In 1931, however, these were abandoned in favour of the establishment of large seed farms at local native council head-quarters, where experimental work is done at the expense of government and seed production is financed by the councils, who also pay the salaries of native demonstrators. The demonstrators are trained at Bukura in the Nyanza Province, where the course lasts for three years and is also designed to fit students to take up peasant holdings. In 1936 there were 157 native demonstrators and grain inspectors at work in Nyanza Province and 173 in the Central Province. In the latter province district education boards¹ employ native instructors who visit schools, lecture, and advise on school garden work. To meet the special circumstances of the Suk in Kenya, a tribe of some 20,000 people in the arid Turkana Province, who were found to be in a chronic state of under-nourishment, a school was opened in 1930, which, besides giving the usual primary education, concentrates on practical instruction in the cultivation of supplementary food crops. The extension through the tribe of the new crops is organized by means of demonstration plots managed by former pupils of the school.

In Uganda agricultural assistants take a five years' course, partly at Makerere² and partly at the Agricultural Department's stations. Instructors receive a shorter training of two months; it has not been found possible to give a longer course owing to the numbers requiring to be trained. At Bukalasa and Serere courses for chiefs, lasting from a fortnight to two months, have been held in connexion with the small-holders' courses, and regular training and refresher courses are arranged for school teachers. African agricultural assistants help in the organization of school gardens.

In Nigeria, in addition to the mixed farming schemes, oil palm demonstration plots have been established by native administrations and at schools. Four students of Yaba College³ were appointed, after a two-year course at Ibadan, as agricultural assistants in 1936. Sir Frank Stockdale is of the opinion that the practical course should be increased to three years, as the training given at Yaba is largely theoretical.⁴ In Nigeria general propaganda

¹ See Chap. XVIII, p. 1230.

² *Ibid.*, p. 1248.

³ See Chap. XVIII, p. 1249.

⁴ *Report*, op. cit., 1936, p. 36.

has been found ineffective; the method preferred is that selected native farmers are induced to undertake trials on their own farms, under the supervision of the agricultural officers, where the results can be observed by their neighbours. Thorough testing in advance of the innovations introduced by this method has been found essential in order to avoid the suspicion of foreign methods which is inevitably created by a failure.¹

In the Gold Coast native agricultural assistants undergo a two years' course at Kumasi, where also courses of four months for farmers are held. In the Gambia special training of an elementary nature has only recently been instituted, and in the Bulok District a scheme has been introduced in collaboration with the native authority whereby model gardens are made at certain villages by the combined work of men from all over the district. In Sierra Leone teachers' courses in agriculture have been instituted, and a four years' training course, of which two years are spent at the Mbang Academy and two at the Njala Experiment Station, has been organized by means of a scholarship scheme.

In French West Africa the training of teachers for rural schools is given at two centres in the Sudan and Guinea, which have been selected as typical of the dry steppe land and the forest belt respectively, where the agricultural methods which it is intended to disseminate may be taught in the appropriate environment. The more advanced regional schools have farms worked on a commercial basis, and ploughs and oxen are lent to selected pupils on leaving, and become their property if they are put to satisfactory use.

Among other means of encouraging the adoption of improvements is the organization of agricultural shows, which have been particularly successful in the Transkeian Territories and the Lake Province of Tanganyika. Similar shows were held in Kenya until the economic depression, and the Nairobi Agricultural Show, though mainly for European produce, has a section for native exhibits. The Transkei has also introduced maize-growing competitions which have resulted in a great improvement in yields.

Some reference to the use of films and broadcasting will be found in a later chapter.²

² See Chap. XVIII, pp. 1297-305.

(c) Smallholdings

In Tanganyika 'ideal holdings' for the demonstration of mixed farming are attached to the experiment station at Lubaga and to all native authority seed farms. Two schemes for organized settlement are now in existence, at Nyamahona, attached to the Ukiriguru experimental station in Mwanza District, and at Kingolwira, attached to the Morogoro station in the Eastern Province. At Nyamahona 10,000 acres have been reserved for controlled settlement, and 140 holdings of 20 acres had been taken up by 1936. The Kingolwira settlement covers some 3,000 acres, and 25 holdings had been allotted by 1936.¹ At the Lubaga station there is an adult school where couples are trained with a view to taking up mixed farming at their own homes.

- In Uganda the training of smallholders was started at the experimental stations at Bukalasa and Serere in 1932-3; holdings vary in size from 8 to 20 acres, and it has been suggested that more effective training could be given with a larger number of small unit holdings.² The native government makes loans for the equipment of persons who have completed the training. The extension of this system is recommended as the only means of development of the densely populated areas of the Eastern Province, but the difficulty has to be met that it is not always possible to obtain sufficient land for an economic holding. For purposes of supervision Sir Frank Stockdale suggested that small settlements are more satisfactory than scattered single holdings.

(d) Control of Plant Pests and Diseases³

Under primitive conditions of agriculture the isolation of cultivated areas provided some protection against the spread of pests and diseases, but the extension of agricultural activities has necessitated the introduction of measures of control. These measures have, in particular, been pressed on administrations where native and European plantations are found in the same area, and certain native crops are thought to be potential sources

¹ For a fuller account, see *Annual Report to the League of Nations on Tanganyika Territory*, 1937, p. 213.

² Sir F. Stockdale, *Report on his Visit to East Africa*, C.A.C. 345, 1937, p. 64.

³ See also E. B. Worthington, *op. cit.*, chaps. vi and x.

of infection. Thus, in Kenya, the cultivation of coffee by natives was, until recently, discouraged, and the areas in which it has now been experimentally introduced do not include the neighbourhood of European plantations.

In the Transkeian Territories the eradication of noxious weeds has been encouraged by means of competitions between the children at different schools. In several of the British territories measures of legal control have been introduced. Thus in Tanganyika, regulations under the Plant Pest and Disease Ordinance¹ of 1921 control the cultivation of tobacco and coffee. The latter empower agricultural officers to order the destruction of plants on unoccupied land, or of diseased crops, to compel growers to keep chemicals for spraying, and to require the eradication of wild plants which may be a source of infection. Native authorities in coffee-growing districts have adopted these regulations and thus become responsible for their enforcement,² and as a result the output and the freedom from pests of native coffee compares favourably with that in European estates, where control is much more difficult to exercise. Cotton cultivation is regulated by a special ordinance³ under which only selected seed may be planted; land on which cotton is grown must be kept free of grass, and insect pests collected and destroyed by fire. After the harvest a fixed date may be prescribed by which all cotton must be uprooted and further planting may be forbidden until another prescribed date. The storing of unginned cotton, except in approved premises, and its removal from one district to another, may also be prohibited. An amendment to the Uganda Cotton Ordinance, giving power to fix dates before and after which planting should be illegal, was recommended in 1936. In this territory the Bugishu Coffee Scheme limits the distribution of seed to farmers whose crops are kept in a satisfactory state. The Native Authority Ordinance provides for the destruction of cotton by a fixed date each season in order to prevent the spread of pink bollworm, and also for the compulsory eradication of coffee infested with pests. The intro-

¹ *Laws*, cap. 77, since replaced by Ordinance 9 of 1937, designed in accordance with the recommendations made at the Conference on the Co-ordination of Agricultural Research and Plant Protection held in 1934. A similar ordinance (24 of 1937) has been introduced in Kenya.

² See Chap. IX, p. 450.

³ *Laws*, cap. 80.

duction of additional control measures, however, has been made difficult by the opposition of the Buganda Lukiko.¹

In the Gold Coast a Plant Pests and Diseases Ordinance was first introduced in 1937, to meet the damage done by a new disease of cacao known as swollen shoot, and by attacks on citrus by fruit-piercing moths. In the Gambia orders of a similar type are issued by native authorities. In the French Cameroons, legislation introduced in 1934 empowers the local authorities to prescribe methods of cultivation or the destruction of infested plants.

VII. THE IMPROVEMENT OF ANIMAL HUSBANDRY

(a) *The Improvement and Conservation of Pasture Land*

Throughout southern and eastern Africa the most serious problem of animal husbandry is overstocking, and the extent to which it exists, and some of the measures taken for checking it, are discussed in the chapter dealing with erosion.² In some parts of East Africa the situation may be more accurately described as an over-concentration of stock in areas which are free from fly and within reach of water, and it is held that the provision of new water supplies would to some extent enable stock to be more evenly distributed; this aspect of the problem is also discussed in another chapter.³ It will be sufficient here to give some examples of the measures taken in typical areas to improve grazing, and to improve stock by culling inferior animals, by preventing disease, and by breeding.

To prevent the exhaustion of the nutritive grasses and the injury done to the soil by constant trampling, it is necessary to introduce some system of rotational grazing by which fixed areas can be kept free of stock until the pasture has had time to recover, and sometimes also to plant rapidly-spreading grasses. The length of time required for recuperation varies, according to local conditions, from six months to eight months or a year, and success depends on the absolute prohibition of grazing during the resting period. In some native areas of the Union this has been enforced by fencing financed from the Soil Erosion Vote, and recovery of

¹ See Chap. IX, pp. 444 ff.

² See Chap. XVI, pp. 1066 ff.

³ See Chap. XV, pp. 1025 ff.

the natural grasses has been found to be very rapid.¹ In many areas, however, the difficulty of reserving reclaimed areas from grazing seriously limits the effect of measures for the control of erosion. In Southern Rhodesia the native reserves are being demarcated into arable and grazing areas. Over a million acres had been dealt with in this way by 1936. In some areas native authorities have co-operated in the necessary measures. Thus, in Basutoland the paramount chief has ordered that areas contoured to prevent erosion should be reserved from grazing. In the Sukuma District of Tanganyika dams have been built for the storage of rain-water in grasslands at a distance from the villages, and as many cattle as possible are sent to pasture there during the rainy season, thus resting the grass around the permanent sources of water near the villages. Over 14,000 acres of home grazing have been reserved by native authorities under this scheme. The Masai are also prepared to adopt the system, and the provision of watering places on this basis has been recommended. In the Kiambu District of Kenya individual natives have spontaneously made paddocks for grazing.

It has been pointed out that the value of improvements in stock is limited so long as the available nutrition is not sufficient to keep them in good condition; and 'the degree of improvement must always be dictated by the plane of nutrition'.² In many parts of Africa there is a severe shortage of food during the dry season, and in some areas the natural pasture has mineral deficiencies which cannot be made up except by hand feeding. In the case of the purely pastoral tribes their contempt for agriculture makes it difficult to persuade them to grow fodder crops. The most extensive pasture research work has been done in the Union of South Africa, and in Kenya, particularly in relation to the problems of European stock owners.³ In the Union research has reached a point where it is possible to recommend with a fair degree of certainty the type of pasture suited to different areas; woolly finger is one of the most important of the varieties indicated. In Kenya there are three grassland improvement stations, at Kabete,

¹ *Report on Native Affairs, 1935-6*, p. 44.

² F. Fraser Darling, *Animal Breeding in the British Empire, 1934*.

³ See above, pp. 945 ff., and p. 949.

Njoro, and Kitale, representing the three main types of climatic conditions; there are also stations at Ngong, Naivasha, and Fort Hall. Among indigenous grasses Kikuyu grass and Rhodes grass have been found useful. The latter can be used for the production of pasture and hay or on disused arable land, and is also drought resistant. In the latter respect the local indigenous star grass has been found superior to introduced varieties. The indigenous clover is expected to prove useful in mixture with Rhodes grass as a pasture legume. In Tanganyika research is still being directed to the determination of pasture species that can be successfully used in rotation.

(b) *Culling*

The compulsory culling of inferior stock has frequently been recommended, but has not so far been imposed owing to the strong dissatisfaction which it would inevitably arouse.¹ The one exception is the Glen Grey District in South Africa, where a proclamation is in force under which poor cattle are branded by the authorities, and must then be disposed of within six months. In the Transkeian Territories General Council proposals to introduce such a measure met with strong opposition. The need for culling has been particularly urged by the Kenya Land Commission of 1933, which recommended the adoption of a definite ratio between land areas and numbers of stock, which should be consistently adhered to.² A Crop Production and Live Stock Ordinance enacted in 1926 made possible the compulsory limitation of live stock in any area, but it was never put into force. A considerable development in marketing facilities has taken place since the Commission issued its report, and some observers believe that the remedy lies in this direction rather than in a compulsory measure of culling. It has been pointed out that a policy of culling of weakened stock can have little effect on quality where, although all animals are stunted, the struggle for existence is so severe that only the hardiest survive. For Swaziland a tax on cattle owned in excess of a fixed number was recommended by Sir Alan Pim.³

¹ For example, destocking measures in the Ukamba reserve have resulted in considerable unrest. See *Manchester Guardian*, August 12, 1938.

² See Chap. XVI, p. 1098, and also *Report of the Kenya Agricultural Commission*, 1929, paras. 126 ff.

³ *Report*, op. cit., Cmd. 4114, 1932, p. 105.

(c) Dipping and Fencing

The most important measures to prevent the spread of disease are dipping and fencing. In the Union of South Africa, dipping is now general among European farmers; it was first introduced in the Transkei during the serious outbreak of East Coast fever in 1900, and by 1932 nearly £1,000,000 had been spent on tank construction and dipping operations. In Southern Rhodesia dipping is compulsory in the wet season. In Northern Rhodesia and Kenya legislation provides that dipping may be made compulsory in areas where the local inhabitants request it. In Northern Rhodesia this has not so far been done, but in Kenya farmers' associations in the Thompson's Falls District in 1936 petitioned for the application of the Cattle Cleansing Ordinance to that area. In Northern Rhodesia a dipping scheme for native areas was introduced in 1930, but abandoned as an economy measure in 1932; there are, however, fifteen dipping tanks in native reserves. In Tanganyika a number of dipping tanks are maintained at their own expense by European farmers, but the opinion has been expressed that in native areas expensive measures for the control of East Coast fever are hardly justified in view of the excessive numbers of stock.¹

In the Union, very considerable progress has, as noted elsewhere,² been made in the paddocking of the lands of European farmers. In the Transkeian Territories the General Council contributes on a £ for £ basis to the cost of fencing schemes undertaken by ten or more contiguous farmers; but individuals who wish to erect fences have to meet the whole cost themselves. Kenya has an ordinance³ which makes fencing compulsory where it is applied, but in view of the great expense which this would impose on farmers it has not been brought into force in any area.

(d) Stock-breeding

Improvements in the quality of native stock can be achieved either by the selective breeding of indigenous strains, or by their admixture with imported stock. In South Africa there seems as

¹ *Annual Report of the Department of Veterinary Science and Animal Husbandry, 1936*, pp. 9-10.

² See Chap. XVI, pp. 1080-1.

³ No. 31 of 1929.

yet to have been no definite decision of policy in this matter. The Afrikander strain has many qualities, among them that of resistance to drought or scarcity conditions; but over a large part of South Africa it has already ceased to be a pure strain. There are considerable differences of opinion as to the extent to which the Afrikander stock, as it exists to-day, is capable of further improvement by selective breeding, or how far a definite admixture of imported strain would be an advantage. Some authorities have expressed the opinion that if more than 50 per cent. of European blood is introduced into native stock there will be a retrogression, due to inability to adapt to difficult environmental conditions. In Southern Rhodesia, however, seven-eighths pure-bred cattle are said to have done well.¹

In the Union, the administration adopted in 1932 the so-called bull and ram camp schemes under which the service of improved sires is provided free for the herds and flocks of native owners. These schemes are in operation in native areas other than the Transkei. In 1936 there were 24 bull camps with 101 bulls, which served about 500 cows, and 3 ram camps with 45 rams. Bulls and rams are purchased for sale to native owners. Bulls are also loaned to farmers who are too far away to bring their cows to the camps. In the Transkei the Tsolo School of Agriculture has concentrated on the breeding of rams for sale to native farmers. The Afrikander breed of cattle is here regarded as the most satisfactory owing to its resistance to disease and ability to forage under stiff conditions.

Sir Alan Pim's reports on the High Commission Territories comment on the nondescript type of native cattle which has developed there owing to indiscriminate mixing with imported types. In Swaziland the government is introducing Dairy Shorthorn blood, and it was suggested in 1932 that if a sufficient improvement in breed was attained there would be a ready demand from European farmers for bullocks in store condition. In Basutoland the introduction of Afrikander cattle was recommended by Sir Alan Pim. The importation of rams other than merinos was forbidden by proclamation in 1927, and a castration campaign against undesirable animals inaugurated at the same time. In Bechuanaland it was held that the effort required to carry out a wholesale

¹ E. B. Worthington, *op. cit.*, chap. xiv.

castration of inferior bulls would be unjustified unless a sufficient supply of fresh blood was available. A grant for the establishment of bull camps was, however, made in 1935.

In the tropical areas there appears to be less hope, except in the highlands, of improvement of stock by the introduction of European breeds, and more attention has accordingly been given to selective breeding of native cattle. The castration of inferior bulls is carried out as widely as possible, but in most native tribes this is still rarely practised except under the direct influence of Veterinary Departments. In Nyasaland it is done by native assistants at the dipping tanks, a method which makes it difficult to combine it with advice on the principles of selection, but it is proposed to establish castration centres under the supervision of veterinary officers. In most territories no clear policy is adopted with regard to the qualities at which breeding is to aim. In Tanganyika native stock has been graded up by crossing with Friesian and Ayrshire cows; the half-grade animals yield more milk and are more tractable. Three-quarter breeds are larger and mature more rapidly, but require correspondingly more food. In Kenya the native herds used at the veterinary training centres are bred up for demonstration to farmers in the neighbourhood.

In Uganda three stock-breeding farms are maintained by the Veterinary Department and two by the native administrations. Only local stock is used and special attention is paid to milking capacity and to the production of draught animals.

In Nigeria experiments are in progress at Shika, near Zaria, for the improvement of three types of native zebu, the white Fulani, Godali, and Shuwa, in order to evolve 'dual purpose' cattle, namely, milking cows and working bullocks for the mixed farming areas. At a stock farm established at Ilorin in 1936, with the assistance of a grant from the Colonial Development Fund, work is in progress on the breeding of a West African shorthorn type suitable for the forest belt; resistance to trypanosomiasis and utility for mixed farming are the main desiderata. Cattle are to be introduced from the Gambia, Gold Coast, and Dahomey, and it is hoped to obtain a small Malinke herd from French Guinea, since this is reported to be superior to any other West African type both in conformation and resistance to disease.

Surplus stock are sold to mixed farmers and are in great demand.

In the Gold Coast Northern Territories the government livestock farm at Pong-Tamale has made similar experiments in selection for resistance to trypanosomiasis. N'Dama cattle from French Guinea have been found resistant to the various strains. Increased beef production is also sought. Improved bulls are issued from Pong-Tamale to ten native administration farms and distributed thence to small farms and village herds. Here the advantages of foreign introductions are questioned by Sir Frank Stockdale, who regards selection from indigenous breeds as preferable.¹

In French West Africa more attention has been given to the breeding of sheep than of cattle. In the wool-producing districts half-bred merino rams are distributed free to native breeders from whose herds ewes have been selected for crossing. The Diré Company has found on its farm at Goundam that half-breed merinos are more resistant to disease than animals with a larger proportion of merino blood. Grading up of native breeds of cattle, horses, and sheep is carried out at the government farm at El Oualadji in the Sudan.

In the Belgian Congo the government farm at Nioka in Ituri is breeding cattle suitable for both milking and beef. Angola cattle have been imported for many years and crossed with European types, but the resultant animals have not the stamina of native types, and attention has more recently been directed to the selective breeding of native stock. In Coquilhatville Province native cattle have been introduced from Dahomey and Conakry.

(e) Training of Africans in Animal Husbandry

Apart from the mixed farming schemes which have been described² there is little provision for special training of Africans in animal husbandry, either as private farmers or as subordinate African staff. In the Union of South Africa practical and theoretical training in animal husbandry is given to young native men at the Fort Cox Agricultural School. In Northern Rhodesia some instruction is given in animal husbandry at the Jeanes and other schools, and in the Barotse Province, where cattle are the main

¹ *Report*, op. cit., C.A.C. 270, 1936, pp. 77-8.

² See also O. T. Faulkner and J. R. Mackie, op. cit., pp. 64 ff.

source of native wealth, it is proposed to incorporate veterinary subjects in school syllabuses.

In Tanganyika a special training course for veterinary assistants already in the employment of the department was instituted in 1936. Small demonstration farms have been established in various parts of the territory, in some cases in connexion with native administration schools. Their principal purpose is to demonstrate methods by which live-stock can be kept without damage to soil fertility. Kenya has five veterinary training centres which give instruction in breeding, disease control, dairying, and the preparation of hides and skins. In Uganda the demonstration farms provide knowledge of improved animal husbandry, and a veterinary school attached to the research laboratory at Entebbe gives a three years' training for native veterinary assistants who have had a preliminary two years at Makerere.¹ Students taking the agricultural courses at Makerere attend lectures and demonstrations on veterinary subjects, and a course of a month for schoolmasters is held annually at Koja Stock Farm.

VIII. SOME FURTHER CONCLUSIONS

It has already been stated that in some areas there is a noticeable neglect of food crops and a concentration on the cultivation of cash crops. To what extent the number of those who no longer grow their food is increasing is not clear, but it is obvious that not only in some areas where considerable incomes can be made from cash crops, but also in territories where peasant producers are rare, large numbers of Africans are becoming permanently detached from food production and dependent on money earned from their labour or from the sale of produce. In times of economic stress they would find themselves destitute or dependent on such food as food growers can share. Reference has been made to the use which it has been necessary to make both in British and Belgian territories of regulations which require natives to grow a minimum of subsistence crops as a protection against scarcity.² These provisions apply, however, to abnormal circumstances. The possibility of increasing detachment from agricultural work and the fact that large numbers of agriculturists are absent from their

¹ See Chap. XVIII, p. 1248.

² See Chap. XI, pp. 630 ff.

villages for long periods in many areas emphasize the need in normal circumstances for encouraging an expansion in the area and in the methods of cultivating food crops.

The general problems arising out of the contact of the simple system of native economy with European influences and modern conditions are discussed in a later chapter,¹ but it may here be remarked that agriculture, in the Union as well as in other territories, remains the predominating occupation of Africans,² and in spite of a gradual increase of the division of labour and of the exchange of products,³ industrial work and wage earning remain a less important part of the whole. How far industrial employ is likely in the future to draw large numbers of workers from agriculture depends on factors over which administrative policy has in actual practice little direct influence. The Union will no doubt continue to stimulate and expand its secondary industries; but for many years to come the African colonial dependencies of Great Britain, France, and Belgium are unlikely to give active encouragement to industries of a type which will compete with their home manufactures. For the present and the near future at all events industry will be chiefly represented by mining, and this has received in the past, and will probably receive in the future, little direct stimulus from government policy. As suggested when discussing the problems of labour,⁴ the question whether preference should be given to a policy of industrial or of agricultural development is one which seldom arises in a direct form, nor can it profitably be considered as a matter of general principle. If the issue arises at all, it usually takes the form of a question whether a particular area should, in view of its health conditions or population statistics, be closed to recruiting,⁵ or should by reason of treaty obligations be protected from prospecting,⁶ or should be reserved from European exploitation in the general interest of the preservation of African social conditions.⁷ In such cases the decision is based on the need for protecting certain concrete interests of Africans, rather than on any consideration of the economic or social value to be attached respectively to industry or agriculture.

⁵ *Ibid.*, pp. 651 ff.

⁶ See Chap. XXII, pp. 1510 ff.

⁷ See Chap. XII, p. 767.

The factors which an administration has to weigh lie, as will have been seen, in the social rather than the economic field, and the practical issue which it has to deliberate is whether or not it should place restrictions on the operation of any particular type of enterprise. Admitting the gravity of the disturbance to many sides of African social life which can be caused by the expansion of industrial employ,¹ even those administrations which are most sincerely concerned to safeguard the interests of African society during its period of adjustment to new conditions, must nevertheless accommodate their policy to the fact that, if the African has to depend only on the results of his agriculture, poverty and malnutrition are, in some parts at all events, likely to continue to hinder him in making any material advance in the standards of life.

There is another issue, of a less general nature, which has taken a prominent place in discussions on agricultural policy, namely, that which relates to the relative merits of development by peasant agency, or by the 'plantation' system.² This term is mostly confined to those undertakings which involve the large-scale employment of non-native capital and management. There will be found in Chapter XX a discussion of the economic factors which apply to this issue, one of the oldest and most widely debated questions of colonial policy; if the subject is further mentioned here, it is mainly in order to point to certain circumstances which must largely limit the range within which an African administration can exercise a choice of policy. In the first place, the issue can hardly be said to arise in such territories as South Africa or Southern Rhodesia; there capitalists have the opportunity of proving, within the non-native area, the extent to which any type of crop can best be produced by the application of 'plantation' methods of cultivation and management. In the second place, there are certain widely-grown products, such as cotton or ground-nuts, which admittedly offer inadequate remuneration for capitalist management, save perhaps in such circumstances as those of the Gezira or Diré;³ and it is probable that cacao must be added

¹ See Chap. XI, *passim*.

² For a description of these systems as applied elsewhere, see H. M. Leake, *Studies in Tropical Land Tenure*, 1933, and H. A. Wyndham, *The Atlantic and Slavery*, 1935, pp. 108 ff. See also S. H. Frankel, *op. cit.*, 1938, chap. iv.

³ See Chap. XV, pp. 1050 and 1053.

to this class. There are, on the other hand, certain crops, such as sisal, tea, or sugar, which can in present conditions be profitably grown only by capitalist methods; this is also true of the raising of quality cattle either for dairying or the beef market. There is a further range of crops, which were at one time thought to be best suited for 'plantation' production, but are now known to be capable of successful production by peasants, provided that cultivation is adequately organized and marketing controlled by state agencies or adequately supervised co-operative institutions; the most typical example of this class is *arabica* coffee. It is a debatable point whether the oil palm is to be considered as best handled under the peasant system or not; indeed, it has been mainly on the oil palm that such controversy as exists on the subject has centred. There are those who maintain that Nigeria would have a more assured position as a producer of palm oil if she possessed a number of plantations similar to those of the *Huileries* in the Belgian Congo;¹ and they point to the increasing share in the world's market now taken by the Netherlands East Indies, owing to the quality of their product. German policy attached value to a system of large plantations as a means to the rapid development of sisal and coffee in Tanganyika, and rubber and bananas in the Cameroons. French policy, which in Equatorial Africa at all events, originally favoured development through large-scale concessions of land and local monopolies over produce, has of late years tended to the grant of concessions to colonists who will make relatively small plantations of bananas, cacao, or rubber; it looks partly to the increase of production, but partly also to their exercising a useful influence on native systems of cultivation.² The Belgian Congo still has some of the large concessions which remain over from the Free State régime,³ and has in late years given the *Huileries* concession for oil palm to which reference has been made above, but is now increasingly inclined to the policy of peasant production. As has been made clear in the course of this chapter, and in that dealing with the problem of land, Great Britain has, apart from the areas which have been colonized, consistently preferred a policy of development through peasant agency.

¹ See above, p. 920, and Chap. XII, p. 793.

² See Chap. XII, p. 787.

³ See Chap. XII, pp. 790-5.

There is, it is obvious, a relatively small field in which the merits of the two systems can come under effective discussion, and in practice the issue seldom calls for decision by an administration unless it is proposed to alienate lands to non-natives for 'plantation' purposes. The field is further restricted by the fact that, in some of the areas in which European capital has sought land for this purpose, as, for example, in Southern Nigeria, it would have been difficult to secure it without some considerable measure of expropriation.¹ The faith of those who at the time considered the balance of advantage to lie with a peasant system was expressed by Sir Hugh Clifford in an address to the Legislative Council of Nigeria in 1920:²

'Agricultural interests in tropical countries which are mainly, or exclusively, in the hands of the native peasantry (*a*) have a firmer root than similar enterprises when owned and managed by Europeans, because they are natural growths, not artificial creations, and are self-supporting, as regards labour, while European plantations can only be maintained by some system of organized immigration or by some form of compulsory labour; (*b*) are incomparably the cheapest instruments for the production of agricultural produce on a larger scale than has yet been devised; and (*c*) are capable of a rapidity of expansion and a progressive increase of output that beggar every record of the past, and are altogether unparalleled in all the long history of European agricultural enterprises in the Tropics.'

It would perhaps be agreed to-day that this statement over-emphasizes the case for the peasant system. The system offers, no doubt, the advantage of the cheapest form of labour, namely that of the family; it is elastic in so far that the native farmer can readily change from one crop to another in accordance with the returns obtained, and in the last resort can revert to food-crop cultivation. Again, the use of co-operative societies and *sociétés de prévoyance*,³ organized instruction, controlled marketing, and grading of produce have removed some part at least of the grounds for the objection that a regular supply of produce of standard quality cannot be expected from independent native growers. But it remains the fact, that in a competitive market, in which

¹ See Chap. XII, p. 770.

² See also Sir H. Duff, 'Cotton-growing in Nigeria', *Empire Cotton-growing Committee*, 1911.

³ See Chap. XXI, pp. 1477 ff.

quality and regularity of supply are of paramount importance, the advantage still seems to rest, in regard to the limited range of crops above mentioned, with the use of capitalist methods. Were it at any time proposed to apply that system on so large a scale as to take up extensive areas of land now occupied by natives, and to convert into wage labourers a considerable section of the present cultivators, British administrations at all events would feel strong objections on political and social grounds, nor would such a procedure be in full accord with the modern tendency of French and Belgian policy. But it is not possible to overlook the advantage which African territories have derived in the past, and can still derive, from the entry into their agricultural economy of a certain element of non-native enterprise. It is noteworthy that Tanganyika, in closing some of its areas to European exploitation, has made a reservation in favour of enterprises which can introduce certain definite advantages in the way of provision of water or the like, and that the Commission on Closer Union in East Africa, while persuaded of the need for providing the fullest safeguards for the native rights in land, nevertheless emphasized the value of the lessons which European systems of cultivation and management had conveyed to natives.¹ In the attitude taken by the Nigerian Government in 1920 there was, no doubt, some apprehension regarding the influence which European capitalist interests might be able to exercise in the affairs of the protectorate. To-day African governments have a more assured position of authority than then, and capitalists have had the experience of the depression period. A scheme for the establishment of 'plantations' on a scale which would assist the economy of an African territory without unduly invading native rights, could now be considered with better understanding on both sides.

¹ *Report*, Cmd. 3234, 1929, p. 20.

CHAPTER XIV

FORESTS

I. THE GENERAL POSITION

THE importance which attaches in Africa to a forestry régime does not lie only in the extent to which timber can be exploited for export or home consumption. There are, it is true, some territories, and more particularly those situated on the West Coast, in which the forests represent a valuable commercial asset. But there are many others in which they have very little commercial value, and their importance lies in the direct protection which they afford to the water-supply or their influence on climatic conditions, both of vital importance to the methods of livelihood of the African communities. Occasion has been taken in the course of a subsequent chapter¹ to refer to some of the scientific aspects of the function which is performed by a permanent or semi-permanent vegetal covering in preventing erosion or soil deterioration, and it is not necessary to deal again here with the matters there discussed. But throughout the world a growing attention is being paid to problems connected with the maintenance of soil fertility, and these questions have a special significance in areas where, as in a large part of Africa, production is already handicapped by deficiencies in the constitution of the soil.² These facts give to the activity of the state forest departments in Africa an importance, as agencies of general welfare, which was not fully appreciated a generation ago. In most territories it is now recognized that the justification for instituting a forest service is not to be found in its ability to pay its own way; the indirect value of forest management to the community is of greater importance than its direct contribution to the general revenues.

It is generally agreed that the greater part of Central Africa was at one time covered by high forest; the surviving forest belt of Central Africa now occupies only about 8 per cent. of the continent's area and has been described as a 'relic of itself'.³ The evi-

¹ Chap. XVI, pp. 1057-63.

² Chap. XIII, pp. 880, 962-4.

³ L. Lavauden, 'The Equatorial Forest of Africa', *Journal of Royal African Society*, Supplement, vol. xxxvi, no. 143, 1937, p. 7.

dence of Roman explorers suggests that it once stretched almost as far north as Khartoum, over 1,500 miles from its present borders. The more obvious cause of progressive deforestation has been native methods of cultivation,¹ which involve the cutting down and burning of high forest, but it remains a matter of conjecture whether other causes have not also operated; it has been suggested that the action of man may not suffice to explain the rapidity of the diminution of the equatorial forest in recent centuries.²

The tropical evergreen forests of Africa are the only ones at present capable of an important export trade in timber to Europe. Those of the Congo, the Ivory Coast, the Cameroons, Nigeria, and the Gold Coast are the most important; those of Kenya and Uganda are smaller in extent. Although luxuriant in vegetation, they are rarely well stocked in the mahoganies, irokos, obeches, and other high-quality or luxury furniture woods which are felled in them. Only the best trees, which have taken hundreds of years to grow, and which would take an equal time to replace, are acceptable on the European market. So far, exploitation has much exceeded replacement; and although progress is being made in the sylviculture of the mahoganies and similar valuable species, it cannot be said of the tropical evergreen forests that their management is understood or practised to any important extent. The work of producing high-grade and luxury timbers for the European market in future is one which, owing to great difficulties in technique, can only be carried out by trained European officers working in forest reserves directly managed by the state; not much can be done by Africans themselves.

In the rest of Africa the prevailing type of woodland is that known as savannah. This extensive area of hardy trees, of indifferently shaped and often swept annually by grass fires, has two important functions. It is now realized that large areas ought to be maintained permanently under trees as protection forest, particularly on hill-sides, catchments, and watersheds. Most savannah soils are of low fertility, easily exhausted and easily eroded if their cover is removed; they are perhaps more a source of danger if abused than a source of direct revenue if well cared for. Once forests of the savannah type have been declared closed to culti-

¹ See Chap. XIII, pp. 879, 885.

² L. Lavauden, *ibid.*

vation as protection forests, their chief need is safeguarding from fire. Methods are being successfully evolved, in some territories, of 'early firing', in which fierce grass fires of the dry seasons are anticipated by a deliberate burning earlier in the year. This is work which the Africans themselves are capable of appreciating and can be taught to practise. The other function of savannah forest has perhaps been less appreciated; it is a basis for native shifting cultivation, quite apart from being the source of all the forest produce upon which the African's existence so largely depends.¹ It may be long before agricultural research will discover means of avoiding the long period of tree fallow which so much of Africa requires between short spells of agricultural cropping, and until this is done it is not easy to see in what manner the savannah can be protected from the invasion due to the practice of shifting cultivation. But it is important to realize that where the practice follows its traditional course, and allows an adequate time for regeneration between periods of burning or cutting, it may be said that the injury done to the savannah is not serious; mischief arises, as has been pointed out elsewhere,² when the 'rest' periods are curtailed, under the influence of causes which are largely connected with the introduction of modern economic conditions. Though, therefore, shifting cultivation has undoubtedly done much to reduce the high forest belt, and has caused the substitution of degraded growths for the original timber, it is possible to exaggerate the harm it may have done in the past, or is now capable of doing, to the savannah growth.³ Certainly no observer can fail to be struck by the enormous areas of savannah still remaining in the Belgian Congo, Tanganyika, Northern Rhodesia, or Nyasaland. The repeated shifting of gardens, while giving the appearance of extensive destruction, generally allows the woodlands more chance of recovery than prolonged cultivation.

It is, of course, a fact that the commercial forests are those of the best quality. Most governments have already begun to make demarcated forests of their best timber areas, to put them under legal protection, and exercise control over their working. Latterly

¹ See Chap. XIII, p. 883.

² See Chap. XVI, p. 1088.

³ C. G. Trapnell and J. N. Clothier, *The Soils, Vegetation and Agricultural Systems of North Western Rhodesia: Report of the Ecological Survey, 1937*, para. 199.

many administrations have tended to place as much importance upon the local marketing of secondary timber species from these forests as upon the export of the most valuable species to Europe. Less advance has been made with protection forests, partly because these are less directly remunerative, and partly also because they cannot be maintained until African public opinion has been educated to appreciate their value. Speaking generally, forestry work in Africa may not unjustly be described as being in its initial stages. In many areas it is still necessary to decide how much of the existing forest needs to be maintained for watershed conservation and the prevention of erosion, for the maintenance of farming operations, particularly in connexion with native subsistence agriculture, for village and town fuel-supplies, and lastly for the growth of timber for use in local industries or for export. Occasion will be taken to discuss at a later stage in this chapter the factors with which an administration must deal in arriving at a decision on these points.

II. FORESTRY WORK IN THE VARIOUS TERRITORIES

(a) *Union of South Africa*

The indigenous timber forests of the Union are estimated to occupy only 778,000 acres, and are confined to the region of constant rainfall in the south and to the seaward slopes and deep kloofs of the southern and eastern escarpments. The need for afforestation has been felt from the earliest period of settlement. In 1690 the Governor of the Cape of Good Hope ordered that 100 young oaks should be planted by every agriculturist. To the early Dutch settlers South Africa also owes the introduction of the stone pine, cluster pine, and a species of poplar; the last proved useful during the War for the match factories of the Union. The modern policy of afforestation dates from 1876, when a grant of £25 was made from public funds 'as a tentative measure towards the renewal of Crown forests under the direction of conservators'.¹ In 1884 the Conservator of Forests at Kingwilliamstown required his foresters to maintain small gardens for raising plants, and three years later the system whereby trees are planted among crops,

¹ *Division of Forestry, Annual Report, U.G. 53, 1937, p. 5.*

known in Burma as *taungya*,¹ was introduced. Burnt forest land was given out to cultivators to clean and plant with mealies or beans, wattle seeds being sown between the rows. This attempt led to more abuse than success. Meanwhile some pine plantations were formed at Knysna. From these unpretentious beginnings plantation work has so far advanced that the state to-day owns 324,535 acres of plantations. It has reclaimed upwards of 28,000 acres of drift sand, much of which is now under trees. Public bodies and private individuals now maintain large plantations of wattle and other trees; that they are still developing their schemes of afforestation is indicated by the fact that 4,000,000 plants were sold from the state forest nurseries in 1937.

The periodic recurrence of drought conditions in the Union,² and the attention which has been directed to the problems of water and soil conservation by recommendations such as those of the Drought Commission of 1923,³ have given public importance to the plantation policy, to which the activity of the forest service is now largely directed. The provincial forestry departments were amalgamated at the time of the Union, and in 1934 the Forest Department was combined with the Department of Agriculture. A Division of Forestry is presided over by a technical officer termed the Director of Forestry. Forests are controlled by a Forest Act,⁴ in the terms of which forest reserves consist of both demarcated and undemarcated reserves, and power is conferred on government to expropriate land for forestal purposes. The Act also deals with the protection of private forests and affords protection to owners who desire it.

The area of Crown lands reserved for forestal purposes amounted in 1936 to 3,173,775 acres, 2,702,460 of which were demarcated forest reserves. 450,000 acres of this total area were indigenous high forest, 309,000 acres afforested land, and 361,000 acres land suitable for afforestation. The remaining 2,054,000 acres were scrub forest and land held for protective purposes. These figures do not include game reserves or the 'national park'. The policy of the Forest Division is, first, the protection of indigenous forests

¹ See G. V. Jacks and R. O. Whyte, *Erosion and Soil Conservation*, Imperial Bureau of Soil Science, Technical Communication No. 36, 1938, p. 34.

² See Chap. XV, p. 1026.

³ See Chap. XVI, p. 1080.

⁴ No. 16 of 1913, amended by 14 of 1917.

so as to increase their future productivity, the revenue derived from these being spent on conservation and regeneration; and secondly to increase the production of timber by plantations of exotic trees. Numerous species, yielding the ordinary softwoods or durable softwoods of the cedar and cypress classes, or durable hardwoods such as eucalyptus, are employed for this purpose. It is estimated that, allowing for afforestation undertaken by public bodies and private persons, the state requires to afforest an average of 20,000 acres of land per annum, but it is doubtful whether sufficient suitable land can be made available. For this and other reasons the annual rate of planting has been stabilized at 16,000 acres per annum. In 1936 the new plantations amounted to about 15,466 acres. Special attention is given to catchment areas, and in pursuance of a resolution in regard to protection of catchments and prevention of veld fires, adopted by the Union Parliament in 1935, suitable land is to be brought for these purposes under the control of the Forest Act, and funds were allocated for work in connexion with the protection of watersheds. The Native Trust and Land Act, 1936,¹ provides that all forests on Crown land in native areas not already demarcated under the Forest Act are vested in the Native Trust. It is also the policy of the Forestry Division to induce farmers and others to plant trees for the purpose of shelter, fuel, and other local uses. The most extensive private plantations, however, are those of black wattle for the production of tan-bark, which amount to 119,606 acres.

The total expenditure of the Forestry Division amounted in 1936-7 to £522,754, and the revenue derived from government areas to £155,589. The European staff consists of 70 officers, including research workers, and 200 European foresters. The higher branches are recruited from students who have completed a four year course in forestry at Stellenbosch University. The Paradys Forest School, situated in a forest reserve near George, provides a two years' course for foresters. Numbers of natives are employed by the department, but no provision appears to be made for special training for them. Considerable research work is carried out at the Forest Products Institute at Pretoria, in the field, and at the Knysna Research Station. Knowledge is accumulating as to the pro-

¹ See Chap. XII, p. 722.

perties and uscs of locally grown exotic and indigenous timbers, and the investigation which is being made in regard to the influence of environment and sylvicultural treatment on the strength of timbers produced in the plantations promises to yield results of importance.

(b) *The High Commission Territories*

Basutoland is characterized by the almost entire absence of indigenous trees, and with the exception of sporadic efforts to plant poplars, the inhabitants have done little or no tree planting in the past. At present animal manure is used for fuel, to the detriment of agriculture, and Administrative Officers are directing efforts towards the growing of trees for fuel-supply. The land tenure system does not, however, encourage individual tree growing. In 1936 11,481 trees were planted in connexion with anti-erosion works. Parts of the Bechuanaland Protectorate are relatively well wooded, and a large quantity of dead wood for fuel is exported by rail from the southern part of the territory to the Transvaal diamond diggings. In the Chobe area, adjacent to the Northern Rhodesia forests,¹ timber is felled under agreement with the government for use as railway sleepers, and in 1935 a forestry officer was appointed to supervise the concession, which extends over 150 square miles of forest. The typical timber tree in this area is Rhodesian teak (*Baikiaea plurijuga*); the average export of timber is some 50,000 hoppus feet per month. No afforestation schemes appear to exist. In Swaziland the low veld is heavily bushed and isolated forests exist in the Drakensburg Range. There are no indigenous timbers in sufficient quantities to repay exploitation, and there appear to be no schemes in operation for afforestation or conservation.

(c) *Southern Rhodesia*

In contrast with the Union, the territory is comparatively well wooded, being covered with trees and shrubs over about 60 per cent. of its area. Except, however, in isolated and favoured spots, trees of large dimensions are found only in the mountain forests and in woods bordering the rivers. The indigenous forests have played an important part in the development of the country, sup-

¹ See below, p. 993.

plying fuel, mine props and timber to the mines, and fuel to the villages and townships, and, until coal was discovered,¹ for the railways. In the early stages of occupation free cutting was permitted to miners and prospectors on unalienated land and in native reserves, but from time to time some measure of control was subsequently instituted. A nursery was started at Salisbury in 1903, and a forestry adviser was appointed in 1912; in 1922 the Mtao forest reserve of 13,137 acres was formed, but no general policy of protection or reafforestation was instituted until after responsible government was established in 1923. A policy of protecting the indigenous savannah forests on Crown lands in three administrative districts was instituted in 1925. In 1927 the Stapleford forest reserve of 60,305 acres was formed, where owing to the comparatively high rainfall (over 40 inches) softwoods, including pines, cypresses, and other conifers, can be grown, and in 1929 about 782,500 acres of tree veld in Matabeleland were taken over. The Mtao reserve, later increased to 15,498 acres, embraces a portion of Mashonaland occupied by Europeans, where hardwoods as well as some softwoods can be grown. By 1930 the area classified as state forest amounted to 4,379,924 acres, of which 666,404 acres were reserved forests, 192,000 unreserved forests, while the greater part, namely, 3,521,520 acres, consisted of national parks and game reserves. In the same year the area afforested with exotic trees amounted to 3,391 acres. In 1938 the Europeans employed on forestry work numbered 44. Trained foresters are drawn from the Union, Conservators are trained mostly at the School of Forestry at Edinburgh. There appears to be no specially trained African staff.

While attention is at present being directed to building up commercial forests for timber, an increased measure of conservation for watershed protection would appear to be actually more urgent, though difficulty is likely to be experienced from the fact that much of the land on watersheds is already in private hands.

(d) *British Colonies and Protectorates*

Before the War there existed no definite scheme for the training of officers for the forest services of the British African dependencies, although Forestry Schools existed at the Universities of Oxford,

¹ See Chap. XXII, pp. 1492, 1495.

Cambridge, and Edinburgh, nor was the local organization of forest work such as to make any material impression on the problems which had to be faced. A proposal to form a forest research institute in Great Britain was made at the Empire Forestry Conference held in London in 1920, and the opening of the Imperial Forestry Institute at Oxford followed in 1924. Candidates for the Colonial Forestry Service are required to possess either a degree of B.Sc. in Forestry or a Science degree and a diploma of Forestry; the centres at which degrees or diplomas of this class may be obtained are the Universities of Oxford, Edinburgh, Aberdeen, and the University College of Bangor. They must take a post-graduate course at the Imperial Forestry Institute, the final year of which is to be completed after a tour of service in Africa. The postponement of the completion of the course until practical experience has been gained of the actual circumstances of Africa is justified by the variety of the forest conditions encountered by recruits in the service of various territories.

The vast areas of thinly populated woodlands in Central Africa present a different problem of control and conservation from that of the more southern areas, where forest lands are less extensive and better defined. Except in the tropical evergreen forests, trees of special value are rarely found in considerable numbers, and their preservation presents considerable difficulties. They are often communal property, liable to be felled by any person desiring ant-proof timber for his hut, a canoe, or even wild honey or fruit, and little can be done for their preservation without the interest of the native authorities and the people themselves. Again, the frequent removal of gardens and villages discourages the introduction of methods such as *taungya*, or the individual planting of trees. Owing to the smallness of forestry staffs and the concentration on urgent problems in connexion with the cutting of timber for industries and for sale, little has been done towards forestry organization in the native areas and, as will be seen, only in Nyasaland has any extensive scheme of communal forests been put into operation. In all territories there appears to be a need for careful reconnaissance, on lines similar to those of the ecological survey carried out in Northern Rhodesia, as a basis for land and forest planning.¹

¹ See C. G. Trapnell and J. N. Clothier, *op. cit.*

The forestry problems of Northern Rhodesia are of an unusual character. At the present time there are three main divisions of forestry work, the Baikiaea or Rhodesian teak forests in the Zambesi valley, the forests in the area near the copper mines, and the reserves required for the provision of fuel for the principal towns. The exploitation of the Baikiaea forests was uncontrolled in its early stages. The concessionary company has now started on the last large area of profitable exploitation, and logging operations on any large scale may be expected to cease in not less than twenty years' time. Had the necessary knowledge and control been available at an earlier stage, the continuity of the forests could probably have been secured, but this is not now feasible, and it is estimated that a period of seventy years' conservation must elapse before the forest is again of commercial value. The present industry employs some 150 Europeans and 4,000 natives and its cessation will be a serious economic loss to the country. As regards timber required for the mines, about 500 square miles in the immediate neighbourhood of the copper mines is held by the mining companies, under tenures permitting timber to be cut on a particular grant for use within the area of the grant only. Besides importing some £80,000 worth of timber annually the mines use great quantities of indigenous timber, particularly for fuel; their total annual consumption is estimated at 320,000 cubic feet. Supplies of major timbers on mine land are scarce owing to uncontrolled and wasteful cutting. A reservation of some 1,200 square miles has been suggested, but in a temporary undertaking given for 1935 it was made clear that any concession that may be granted may not cover the whole of the area. The method of exploitation without regard to regeneration hitherto followed shows the necessity for proper working conditions, and the preliminary operations of reconnaissance, and the subsequent supervision of cutting and the like, will cause a considerable increase in the work of the forestry staff. The forests in the mining regions have a low yield of useful timber and present a large number of silvicultural problems. Work has been concentrated for the present on problems of regeneration and a number of experiments have been carried out; planting trials include indigenous species and Mexican pitch pines. One private factory has devoted attention to the possibilities of the commercial

use of indigenous woods, but much further study is required.¹ So far as fuel supplies for the towns are concerned, the destruction of woodland for fuel is common in the vicinity of towns as well as mines; thus at Broken Hill every tree within an area of thirty square miles has been destroyed. Forest reserves are being laid out to preserve future fuel supplies. So far little has been done to preserve timber in catchment areas, and the single reserve for this purpose is of a nominal character.

The Forests Ordinance² allows for the control of forest lands and the protection of certain trees: the area gazetted as state reserves amounts to 575 square miles. The forestry staff in 1936 consisted of 3 European Conservators, 1 European forester, and 35 forest guards. No African foresters are employed or are in training. Little responsibility is assumed by the native authorities for forest protection. At present it would not appear that there is any urgent need for the control of the cutting of woodland for garden or other purposes, save in cases where the destruction of timber of potential economic value is involved. For this purpose, and also to decide what areas are required for the purpose of water conservation, a careful survey of the territory is required.³

Nyasaland is comparatively well wooded, the forests occupying 11.8 per cent. of its area, but, as in other territories where shifting cultivation is practised, there has been much degradation of the original woodlands. The forest reserves now number 48, with an approximate total area of 2,623 square miles, which is equivalent to 7 per cent. of the land area of the protectorate. The reserves cover the major catchment areas and watersheds. Protection of stream banks and hill slopes is provided for by legislation,⁴ but further control appears to be necessary to ensure the preservation of natural vegetation on the poorer soils of the country. Moreover, in opening up land for agriculture it seems advisable under local conditions to preserve sufficient belts of forest and natural vegetation to form wind breaks for the conservation of soil moisture and the prevention of wind erosion. Since 1926 a scheme for the formation of village forests by allocating an area near villages to be

¹ *Report on the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, p. 249.

² No. 21 of 1925.

³ See C. G. Trapnell and J. N. Clothier, *op. cit.*, para. 200.

⁴ Forest (Amendment) Ordinance, 1936.

maintained under forest, has been in operation, with the primary object of providing supplies of firewood. The scheme aims at demarcating 2 acres of forest land for each family; seedlings are issued by the government, and the village headmen, assisted by African foresters, are held responsible for their care and upkeep. At first the scheme was not popular, but in 1930 a District Officer was seconded for six months to explain its advantages to the natives, and by 1936 well over 3,000 village forest areas had been demarcated.¹ The scheme follows in some respects the practice in parts of India and resembles the communal forests in France, such as in the Auvergne. Provision is also being made for the demarcation and protection of selected forests and woodlands by native authorities; they are intended to be supplementary to the state forests, but in no way to supersede the village forests for village needs. Their area is given as 250 square miles.

Forestry is controlled by Ordinance 12 of 1926, which is administered to a great extent by the native courts, and in 1935 about 88 per cent. of the 3,469 convictions under the Ordinance were dealt with by them. The forestry staff consisted in 1936 of 6 Europeans, 1 of whom is engaged in research, and 1 forester. The African staff comprised 33 foresters, who are trained in the field and in a special course at Limbe. There were also 82 African forest guards. Observations and experiments in silviculture are being made with regard to natural regeneration, also with species of exotics such as pines, which show promise since the inoculation of soils with mycorrhiza was begun. The value of exported timber in 1936 was £25,964 and of imported £24,392.

The original forests of Tanganyika Territory had been seriously reduced long before European occupation; climatic and soil conditions postulate the previous existence of areas of evergreen forest of which only small traces now remain. The area of state forest reserves, which amounts to 4,060 square miles, covers less than 1.5 per cent. of the total land area of the territory. There are 322 square miles of 'close' forest awaiting reservation. In addition to 107 square miles of native communal forests there are 172 square miles of non-native privately owned forests. These figures include nearly all the remnants of evergreen forest in mountain country

¹ *Nyasaland Forestry Department, Annual Report, 1936, para. 50.*

and round the head waters of rivers and streams. A few small experimental reserves and plantations, on the lines of the village forests in Nyasaland, have been formed under the native authorities to provide poles and fuel for villages where supplies are in danger of exhaustion, but it remains to be seen whether the native authorities will in fact be capable of controlling cutting so as to maintain a permanent supply. The *taungya* method has been used for replanting, and in Kwimba District, where the problem of wind erosion exists, strip plantations have been established in echelon formation as wind breaks. In the Forest Rules (8 of 1933) power is granted to Administrative Officers to prohibit the destruction of trees on the upper slopes of mountains and hills and on the banks of streams; Rule 6 provides against the clearing of private forests, but is difficult to enforce owing to lack of establishment. An increasing use is being made of native authorities to enact regulations to prevent the destruction of trees near the banks of streams and on the tops of hills.¹ Four areas in the forest reserves are being exploited by seventeen saw-mills, including those belonging to the gold-mining industry, and working plans have been prepared which prescribe regeneration by planting. One of these mills operates with a view to starting an export business.

Very large free issues of timber are made to the gold mines which hold extensive forest concessions. The exports of timber were valued at £15,000 in 1936 and imports at £22,000. The staff consists of 8 European Conservators, 9 European foresters, 1 African forest ranger, and 148 African forest guards. The African staff is to be trained in future in a Rangers' School at Aroscha opened in 1936. The establishment has proved inadequate to cope with the rapidly increasing demands; wastage of timber resources and leakage of forest revenue have resulted, and it has not been possible to introduce systematic forestry into several large areas of the territory, notably into the western and southern areas. In 1936 there were, indeed, no specialist officers such as silviculturists, and specialist work cannot be carried out by officers who are almost solely occupied with routine duties. The area is,

¹ E. Harrison, *Soil Erosion, Tanganyika Territory, 1937*, pp. 20-2; see also *Report to the League of Nations on Tanganyika Territory, 1937*, pp. 231-3.

moreover, one in which preservation of forestal growth is of unusual importance, owing to the length of the dry season. It may be noted that the recent grant of £57,570 from the Colonial Development Fund was intended for a joint scheme of forest preservation and water supply.

In Kenya rapid destruction of the high forests was going on when European occupation first began. Though reservation began in 1901, the process of deforestation continued actively until demarcation reached an advanced stage in 1911. The relics of the ever-green forest have been reserved as Crown forests, but shifting cultivation can be practised locally in the regenerated areas under licence, and excisions have been made from time to time; for instance, one excision of 13,500 acres was recommended by the Kenya Land Commission of 1933.¹ Excluding savannah, the remaining forest land only amounts to 2 per cent. of the total land area of the country, and it would appear desirable to avoid further excisions if possible. In the native reserved areas large tracts have been denuded of forest.² In the early days of the administration the forests which clothe the sides of Mount Kenya stretched, on the southern side, almost to the edge of the Masai plains. Elimination of Masai raiding by the British left the Kikuyu free to attack the trees, and until the demarcation of the forest in 1911, and to some extent afterwards, its edge was steadily pushed back. It has been estimated that the Kikuyu destroyed at least 1,000 square miles of forest before demarcation. Reafforestation is hindered by the difficulty of obtaining the consent of the natives themselves to the reservation of their lands for the purpose. A system of *taungya* has been adopted by the Department in the forest reserves, and in the Kiambu District the growing of introduced wattles³ is solving the question of fuel supplies. Exploitation is being undertaken by several saw-mill firms. The exports of timber were valued at £25,031 in 1936 and imports at £18,301, excluding box boards. The total area of forest reserves amounted in 1936 to 5,231 square miles, of which 371 square miles are on native lands. Certain outlying forests, particularly the large Masai forests, are still unprotected. Kenya has a gazetted staff of 9 officers, with 32

¹ Cmd. 4556, 1934, pp. 132-3.

² See Chap. XVI, p. 1096.

³ See below, p. 1014.

N.C.O. rangers and foresters, of whom 16 are European. The extension of conservation depends partly on the increase of staff, but much also remains to be done to educate native opinion, in order to secure a larger measure of assistance from the native councils.

In Uganda little is left of the original flora of the large forests which once covered the country, except in a few small areas such as parts of the Budongo forest, and on the high mountains. Deforestation of the more heavily covered areas, such as the slopes of Mounts Ruwenzori and Elgon, was already in progress when the country was first observed in 1896. This destruction of the old forests may be offset to a certain degree by the planting work now being carried out under the supervision of Administrative Officers, with funds from the native administrations, and by Forest Department staff, but it is by no means certain that the destruction of indigenous forest can be made good by replanting. In the lower areas the destruction of the savannah has been accelerated by the introduction of cotton cultivation,¹ and the denudation of the vegetation has produced in many districts a serious condition of erosion. In the Teso District alone it has been estimated that some 40,000 acres of savannah are cleared each year for cotton planting. The Forestry Department dates from 1917. In 1936 the staff consisted of 8 Conservators, 6 European foresters, and 42 African foresters or rangers; the African staff is trained at the Kiterera Forestry School. It is also proposed that an inter-territorial forestry school should be established as a branch of the Higher College which it is proposed to institute at Makerere. The native administration forestry headmen are given practical training at two forest stations; about ten of these have already been trained and work under the native administrations. For many years some native administrations have made small plantations for the supply of poles and fuel, and it is the policy of the Department of Forestry to build up an understanding among the Africans of the value of forests. It is also its policy to increase the reserved forest areas from the present area of 2,812 square miles to 10,000 square miles, including savannah forests, or 12.4 per cent. of the land area, and to exploit commercially the state forests. The exports of timber

¹ See Chap. XIII, p. 904, and Chap. XVI, pp. 1099-1101.

were valued at £14,145 in 1937 and the imports, mostly from Kenya, at £6,925.

In Nigeria, large areas of savannah forest cover the Northern Provinces and the northern parts of the Southern Provinces, and are subject to the usual shifting cultivation and annual firing. In the north the climate is dry and the proximity of the Sahara has raised problems of sand penetration. Here many cultivators may, owing to the prevalence of blown sand at sowing time, have to re-sow their seed three or four times, or even as much as ten times in bad years.¹ The theory of continuous southward encroachment of the Sahara is now, however, no longer universally accepted.² The areas of deforested farmland along the international boundary may give a wrong impression, but they are only an interruption of the savannah, which continues again farther north. But though it is not proved that aridity is progressively increasing, the irregular rainfall and lack of drainage produce oscillations and temporary extensions of the desert to the south, and it is necessary to devise means for protecting agriculture. Reservation of the savannah forest to form belts against the prevailing wind and blown sand, and above all the prevention of the annual firing of the countryside, have been suggested as practical measures which cost little, but they admittedly constitute interference with the practices of the people. Some experiments have been made with a process of strip plantations in echelon formation in the Emirate of Katsina. The work proved expensive, and difficulties were experienced in obtaining land from the native administration; this operation would also have been on far too small a scale to have had much effect on the problem of shifting sand. An experimental planting of Dom palm (*Hyphaene thebaica* Mart.) to form a barrier along the international frontier has met with some success.³ It may possibly prove to be more important to provide water supplies and plant good grasses in forest reserves in this district than to encourage tree growth.

The more immediate results are appreciated by the inhabitants, who are accordingly readier to co-operate. Forest officers are now engaged in studying the desiccation question, and are making regional surveys in Northern Nigeria.

In the Southern Provinces of Nigeria the traditional system of cultivation differs from the more rapidly shifting system used elsewhere, but nevertheless involves much destruction of high forest. It was stated some years ago that cultivation on the northern and eastern borders of the high forest zone was resulting in a recession of forest at the estimated rate of 1,000 square miles a year. The matter is serious, for the destruction of the forest seems already to have had grave consequences on the cacao plantations of the western provinces. The introduction of *taungya* methods has been attempted, but it has not so far proved a marked success, as cultivators cannot be induced to do the planting, which has to be undertaken by the Department. Both the research silviculturists have been engaged in introducing this method, and examples are to be seen at Sapoba near Benin and at Mamu near Ibadan, but the view that reafforestation should by this means keep pace with destruction appears optimistic.

So far, most attention has been paid to the forests of the Southern Provinces, where the greater proportion of the staff has until recently been concentrated. Here the development of commercial timber production has to some extent overshadowed the important work of forest reservation, which has further been handicapped by the necessity for obtaining the consent of the native authorities, all land being here regarded as native property.¹ The total area reserved in Nigeria is 18,116 square miles;² until recently little had been done towards the reservation of areas of savannah forest. The aim is to attain a minimum reserved area of permanent forest of 25 per cent. of the total land area. This figure is based on proposals put forward some years ago, but, having regard to the increasing extent of erosion, there are some officers who consider that under present circumstances an even higher percentage is now desirable.

While in Northern Nigeria the government is not hampered

¹ For land system, see Chap. XII, pp. 768-74.

² Native Administrations, 11, 118, Government, 6, 998.

by the existence of rights which would make reservation legally difficult, in Southern Nigeria the general recognition that the lands are native property creates a different position. It was originally decided that forest lands could only be reserved by agreement with the native administrations; the agreement laid down the scale on which any royalties received should be distributed as between individual occupiers and the native treasury.¹ The slow progress made in achieving agreements led to the extension to the whole territory of the Forestry Ordinance of 1916,² which gave the government power to create a forest reserve, in the event of failure to reach agreement. Persons claiming rights over the land, and dissatisfied with the administrative award of compensation, can appeal to the courts. A certain number of reserves have been created in the Southern Provinces under this procedure. The reserves created under the ordinance are distinct from those created by native administrations under the Native Authority Rules. These are managed by the native administrations themselves with their own guards, and constitute a more popular method of reservation than that provided by the Ordinance, though the actual management is far less regular. Of recent years the administration has also decided to place selected state reserves under the management of native administrations, giving the latter a share in the net proceeds after paying costs of management. So far, the action has been taken only in the case of a reserve at Benin,³ measuring about 1,000 square miles.

A series of small communal reserves are being constituted for local supplies of fuel and timber, as in the Tiv Division, Benue Province. The burning of bush in the Northern Provinces, in connexion with tsetse-fly control, has occupied the attention of the Forest Department here as in other colonies; the fly may be exterminated, but the resulting deforestation may form the starting-point of new erosion. On the eastern slopes of the Udi plateau in the south-east erosion is being counter-attacked by the Forest Department on the lines of the reafforestation work carried on at Etawah, United Provinces, India, though on a much smaller scale.

¹ *The Forestry Manual*, 1924, p. 892.

² *Laws of Nigeria*, 1923, vol. iii, cap. 95.

³ See Chap. IX, p. 430.

In 1936 the forestry staff consisted of 51 European Conservators including 3 research officers, 1 European forester and 3 surveyors, and 41 African rangers or foresters. It is proposed to employ a few African candidates from Yaba College¹ and train them in a forestry school to be started at Ibadan.

In the Gold Coast the northern border of the high forest is receding, as in Nigeria and the Ivory Coast on the west, while within the forest belt farther south extensive areas (the total of which has been put as high as 1,000,000 acres) have been cleared for the cultivation of cacao;² other areas have been denuded to supply the mines, several of which possess concessions to cut timber. The area of high forest remaining to-day is less than 14,000 square miles; it is estimated that about 290 square miles are destroyed yearly, and that if the present rate of destruction is maintained, little will survive in fifty years' time. The securing of forest reserves is attained under the Forests Ordinance³ either by direct government reservation or by reservation under rules by the chief. The events leading up to the passing of this Ordinance form part of the political history of the territory.⁴ In 1911 a Forest Law was passed, providing for the establishment of government reserves, but was withdrawn on the opposition of the Aborigines Rights Protection Society, based on the ground that it was an invasion of 'stool' rights. After the War the chiefs were urged to establish 'stool' reserves through by-laws, but by 1926 only 240 square miles had been reserved, although 6,000 were considered necessary.⁵ In 1926, despite native opposition, a Forestry Bill was passed and became law; it provided that government should constitute reserves, but that they should continue to be the property of the stools. The policy has not been a success, for where reserves come within the jurisdiction of the native courts low penalties are given for infringements and the purpose of reservations is largely negated.

Owing to the former paucity of staff the Forest Department has concentrated on work in the south of the territory; only 2,436

⁵ Sir F. G. Guggisberg, *The Gold Coast. A Review of the Events of 1920-6, and the Prospects for 1927-8*, 1927, p. 64.

square miles of reserves exist, but an attempt is now being made to extend this area to some 8,000 square miles, exclusive of savannah forest. The difficulty of obtaining this land is, however, obvious; if the object is achieved no more timber forest land will be available for extension of cultivation after twenty-five years. Proposals for reservation follow the lines of protection belts for West Africa suggested by Professor Stebbing.¹ Briefly, the plan is to enlarge existing reserves and establish new ones in such a way as to form a northern protective belt; to protect all the principal watersheds; to establish a belt of permanent forest on the hilly escarpment forming the north-east limit of the high forest region (which is also the region of cacao cultivation, and is the watershed between the Pra to the south and tributaries of the Volta to the north); and to form a series of shelter belts in the high forest (closed forest) region in order to protect the cacao cultivation, and small reserves near townships to supply local requirements. The cacao plantations need protection if they are to survive, and protection by forest belts, with the added safeguarding of the water supplies, appears to be a possible solution and as a beginning is not unduly costly. It has quite recently been decided to enforce the maintenance of shelter belts and so-called shade trees by the cultivators of cacao. The staff consists of 22 European Conservators, 64 African rangers and foresters, and 200 African forest guards. Exports of timber were valued at £119,795 and imports at £11,759.

Sierra Leone has practically lost its high forest belt. There are now only 765·25 square miles of reserved forest, representing 2·74 per cent. of the total land area. The unreserved primeval forest is being reduced every year, and the secondary forest which had replaced it is steadily deteriorating. In the south a rapidly increasing population has produced the usual result; the rotation of felling the savannah, now reduced to a mere scrub in parts, is as low as four years or even less. In the prevailing climate, soil, uncovered by forest, is reduced to sheet laterite, which has a poor value for cultivation purposes. In the Colony the forest reserves are on Crown lands, but in the Protectorate reserves may only be created if the chief and his council request the state to do so;² thus,

¹ E. P. Stebbing, *The Forests of West Africa and the Sahara*, 1937, pp. 37-47.

² For land system, see Chap. XII, pp. 780-2.

while in the Colony the reserved area amounts to 28·8 per cent., that in the Northern Province is 1·4 per cent., and in the Southern Province 3·6 per cent. of the total area. The forestry policy is to postpone the creation of new reserves under the Forestry Ordinance of 1924, in view of the smallness and remoteness of remaining areas of virgin forest and the high cost of reservation; the administrative staff is to exercise its influence with the chiefs to prevent unnecessary destruction. In order to reduce the cost of forestry, existing forests are to be improved for commercial exploitation, and in selecting areas for reafforestation, land which has passed out of cultivation is to be chosen. The activities of the Department are therefore largely directed towards the improvement of the stocking of accessible parts of existing reserves by natural regeneration. A forest nursery was established at Tabe (now being removed elsewhere) and *taungya* plantation work has been begun; some remarkable results have been obtained with *Gmelina* (an exotic from India) and *Cassia*. Experiments are also being undertaken at the Agricultural Research Station of Njala. The staff of the departments consists of 5 European Conservators, 4 African rangers or foresters, and a number of forest guards.

(e) *French Territories*

The French forest service in Africa was organized under a Decree of July 18, 1923, which envisaged a service similar to that of the mother country. Forest officers are recruited from the home service, or from candidates who have passed through the *École Nationale des Eaux et Forêts de Nancy*. A lower grade of *contrôleurs* was established by a Decree of the Governor-General of French West Africa in 1932. These are trained for two years at an agricultural college, and then for a period in France at the Forest School at Barre. Only in the Ivory Coast has a complete forestry service been established, but it cannot be said that the vast areas of forest in that territory have as yet been brought under complete control. In 1934 there were 5 Forestry Officers, 12 *contrôleurs*, and 35 African forest guards. It is noteworthy that the Forestry Officers are placed for administrative purposes under the control of the District Administrator.¹

¹ See Chap. VI, pp. 236-41.

The areas of reserved forests of all types are as follows:

French West Africa	.	.	.	1,400,000 hectares
Cameroons	.	.	.	200,000 „
Equatorial Africa	.	.	.	350,000 „

The forests of the Ivory Coast are probably in as favourable a position as in any other part of Africa.¹ There has been relatively little pressure of population on the soil, and it is only in late years that serious attention has been directed to the possibility of growing marketable crops, such as cacao and coffee. As a consequence the colony is still rich in commercial high forest, and the degradation of the savannah forest to the north of it does not appear to have proceeded so far as in the British colonies. It still contains a large percentage of scattered old trees, the relics of the former high forest. The exploitation of forests in the Ivory Coast dates from the early years of the century, and for some years created a serious labour problem. For some time 15,000 men were employed; communications and living conditions were bad, and recruits were only obtained under administrative pressure. Government reports spoke of grave social disorganization in the recruiting areas, and there was a high percentage of desertions from the forests. A reduction in the scale of exploitation, improvement in communications, and the activity of the state inspectorate have greatly reduced the scale of the labour problem. The forest service was created in 1925. The management of the forests is now regulated by government decree.² By 1930, 33 concessionaires exploited 33 areas of 2,500 hectares each, most of which belonged to five private companies. In 1930, 26,586 trees were felled, 12,000 of which were mahogany. The *Compagnie Forestière Équatoriale* lease concessions amounting to 100,000 hectares. There are 17 saw-mills working in the colony, 5 at the capital, Abidjan, of which 2 are government mills, and 1 in each of the more important districts, to supply local demands for converted material. The cost of exploitation is increased year by year by the need to cut at greater distances from the lines of communication. The period during which exploitation on the present lines is possible is estimated at seventy-five

¹ The Ivory Coast has 40,000 square miles of rain forest.

² Decree of June 18, 1912, *arrêté* of March 22, 1927.

years, and some remarkable efforts are now being directed towards regenerating the regions from which trees of value have been cut; there are some areas which have been completely denuded of mahogany and the more valuable species of timber.

The provisions of the Decree of 1912, which aim at the limitation of cultivation near villages to preserve woodlands, have not been enforced, possibly owing to difficulties of control. The importance of native co-operation in forestry work is recognized, and a circular issued by the Governor of the Ivory Coast in 1934 describes the afforestation work done by the native communities in the savannah areas. The north of the colony has been divided into three regions, with the object of forming village plantations, and the species to be employed were laid down for each region. The project is supervised by the Forestry Department and is said to have met with considerable success.

Forest reservation is still in progress, but no large-scale reservations in the savannah forest have yet been considered. Old trees of valuable species standing in the savannah regions are marked by the forest staff for reservation and used as seed-bearers, the seed required by the Department being collected by the villagers under the orders of the Administrative Officers. A scheme for forming plantations for the supply of fuel for the railway has been started in the savannah regions, teak, *Cassia*, and *Dalbergia sissoo* being amongst the exotics planted.

In Togo the Germans began a scheme of plantations in the savannah regions under which an area of 80,000 hectares was to be replanted. By 1914 about 3,000 hectares had been planted, but the results, even allowing for the want of supervision during the War years and the damage done by fire during that period, were on the whole disappointing, possibly owing to inexperience in tropical soils and species. The chief species planted were teak, the mahoganies (*Khaya senegalensis* and *grandifoliola*), and iroko (*Chlorophora excelsa*). It is interesting to note that the Germans made use of two methods, the 2 m. \times 2 m. planting, and the line method in which they cut lines 2 m. apart and 0.50 m. wide, cleaning the line and sowing seed. The French appear to have adopted these methods with modifications, and in the operations undertaken in the Ivory Coast, where the rain and deciduous forests present more favour-

able conditions for regeneration, have met with considerable success.

In the Cameroons, as in Togo, all forest lands are held to be Crown property, as being *vacantes et sans maître*.¹ The grant of concessions is regulated by decree,² and for some years the exploitation of the high forest for valuable timbers has been in progress. Sylvicultural work has also been undertaken on lines similar to those adopted on the Ivory Coast. In the savannah regions the policy is to reserve all areas of high forest still existing, and to create plantations for the provision of fuel and for climatic and protective purposes. Proposals have been made³ for the protection of from a quarter to a third of the total savannah region, but it is not known how far this scheme takes account of the requirements of local cultivation.

An interesting point arising from the sylvicultural work in the high-forest belt is the question of replacing the valuable timber species removed in the course of exploitation. In some quarters it is held that the present work will result in the formation of dense almost pure crops of valuable species, but in others it is held that if the balance in the rain-forest belt is upset by attempts to raise only valuable timbers, soil and moisture may be adversely affected.

(f) *Belgian Congo*

Difficulties of transport have in the past stood in the way of the commercial exploitation of forests. This has been regulated by decree since 1934,⁴ but a government forestry service and a general forestry policy were not formed until 1936, when Forestry Officers were appointed to most of the provincial head-quarters. In 1937 these numbered six and are technical advisers to the commercial companies holding concessions, as well as conservators of the forests in native areas. They are assisted by some forty-six African forest guards. The *Comité Spécial* of Katanga has for some years had its own forest service. The reservation of forests is also in an early stage. One hundred and three reservations have been

¹ See Chap. XII, p. 789.

⁴ Decree of April 4, 1934.

made, some to conserve watersheds, and others to prevent the destruction of forests along motor roads.

Reafforestation is attempted mostly in the eastern provinces of the territory. Proposals are under consideration for the inclusion of afforestation in 'educative' agricultural work,¹ but in the Kivu District afforestation is said to have been undertaken voluntarily in certain areas and 600 hectares of trees have been planted. It is proposed to extend a system resembling *taungya*, which is used by the Nkunku people in the Inkisi and Natadi areas, who plant the seeds of indigenous trees and strip cuttings of other acclimatized trees on fallow land to restore the fertility of the soil. Certain of the concessionary wood-cutting companies undertake afforestation. Thus *Agrifor* and *Afco* are attempting plantations of *Limba* in the Mayumbe District; in the Kasai Province, *Exforka* and the *Forminière* regenerate their forests with *Tectona grandis* and other exotic species. Near Léopoldville *Otraco* has plantations, and other privately-owned plantations exist in the Kibali-Ituri, the Kivu, and Élisabethville areas. The *Inéac*² is organizing a forestry station at Yangambi and has undertaken a forestry reconnaissance of the region. The station will maintain a seed nursery and carry on research work.

The concessions for commercial exploitation amount to 103,000 hectares.

III. ORGANIZATIONS FOR FORESTRY RESEARCH

The research work in Great Britain is practically confined to timbers for commercial exploitation. The Imperial Forestry Institute³ at Oxford forms a centre for advanced studies and a bureau for information and for the identification of woods. Its members visit African territories and have made some valuable reports. A series of publications entitled *Forest Trees and Timbers of the British Empire* is issued from time to time. A Colonial Forest Resources Development Department was formed in 1936, financed by the Colonial Office. It is in close relation with the Forest Products Research Laboratory at Princes Risborough. This laboratory, which is a research establishment of the Department

¹ See Chap. XI, p. 630.

² See Chap. XIII, p. 953.

³ See above, p. 992.

of Scientific and Industrial Research, is concerned with research on wood and wood products. The laboratory undertakes the testing of timbers, and tests have been made for all the African colonies. The Advisory Committee on Timbers at the Imperial Institute in South Kensington is composed of members of the wood-using trades, and concerns itself mainly with questions relating to the development of trade; it works in co-operation with the Colonial Forest Resources Development department, and has issued publications on some African timbers. The Empire Forestry Conferences are held every five years and form a valuable link between Forestry Officers in various territories. Reference will be made at a later stage in this chapter to the question of co-ordinating the work of local officers engaged in research.

In the Union of South Africa, which is now self-contained in these matters, extensive silvicultural work is done, and research is carried out in connexion with the Forests Products Research Institution at Pretoria, which is equipped for the study of seasoning problems; experiments in the treatment of timbers against decay from fungus or insect pests are conducted in the Botanical Department of the University of the Witwatersrand. The Botanical Department at Stellenbosch University also collaborates with the pathological section of the Division of Plant Industry in the investigation of tree diseases. The forest service of the Union contains thirteen specialist research officers.

Forestry work in the French territories is co-ordinated by a Forestry Adviser attached to the Governor-General at Dakar. The official propaganda and information bureau called the *Agence Économique* deals with the French colonies and with the mandated territories of Togo and the Cameroons. It has nothing to do with trade in timber. The *Comité National des Bois Coloniaux* is a private organization dealing with tropical timbers from the point of view of scientific research and economic value, but it, too, is not concerned with trade.

In the Belgian Congo there is a forestry adviser for the whole colony. There is no separate provision made for research into colonial products, but an organization called the *Union Professionnelle des Producteurs de Bois Congolais* deals with the marketing of forest produce.

IV. FOREST BOTANY, ECOLOGY, AND STOCK-TAKING.

Botanical knowledge of the African forest is now well advanced; indeed, both in British and French circles some doubt has been expressed whether undue attention has not been paid to this one class of work. In the British territories the first study on the subject was that of F. Lely, dealing with the useful trees of Nigeria. The Imperial Forestry Institute has subsequently compiled a body of useful information from the specimens and other data supplied by British Forest Officers. This takes in the first instance the form of check lists; these in turn should lead up to annotated catalogues, and finally to regional floras. The first Imperial Forestry Institute list by Burt Davy and Bolton (1935) deals with Uganda, and the authors, in collaboration with members of the Uganda Forestry Department, show that 1,146 indigenous species are represented in that country. In 1934 the Uganda Forest Department itself issued a list of the native names of trees and shrubs in Uganda. The second list by Burt Davy and Hoyle (1937) includes all recorded trees from Nyasaland, and a third list for Nigeria, still in manuscript, contains 1,240 species and varieties representing a 50 per cent. increase over a first list published in 1914. Mr. J. D. Kennedy, silviculturist in the Forestry Department of Nigeria, has collected a large number of species in the colony, and published in 1936 a useful book on the forest flora of Southern Nigeria dealing with over 1,000 species, including 17 new species and 1 new genus.

The stock-taking, or enumeration of marketable species, forms an important part of the District Forest Officer's work. In South Africa the determination of all indigenous and introduced forest trees is undertaken by the Forest Research Section in co-operation with botanists of the Division of Plant Industry, and very few trees, if any, remain unidentified. A number of official bulletins have been published by the Division of Forestry giving the results of research and experience.¹ In Southern Rhodesia a vegetation map has been prepared distinguishing the main physiognomic types. In Northern Rhodesia a detailed ecological survey gives valuable information.² In Nyasaland a general reconnaissance of forest

¹ See *Division of Forestry Annual Report*, 1936, p. 33.

² A. G. Trapnell and J. N. Clothier, *op. cit.*

areas is complete, ecological investigation has been started, using soil classification as a basis, and simple working plans for village forests are being prepared. In Tanganyika Territory more is known about forest vegetation than in most other parts of East Africa, as a result of identification of species, general reconnaissance in connexion with the land development survey,¹ and ecological investigation of the Tsetse Research Department.² The enumeration of forest-growing stock has been carried out with reference to nearly all the Kilimanjaro and Minziro forests, most of the Shume-Magamba forests, some of those of Meru, and considerable areas of forests on public lands, containing stocks of *Chlorophora* and *Khaya*. In Kenya the identification of species in the forests is practically complete, but no wide-scale stock-taking has been done. Working plans are restricted to those forest areas which are at present under exploitation and to the considerable area of plantations. In Uganda a working plan has been drawn up for the Budongo forest as a result of aerial photographs which have revealed the extent of growing stock. This and Northern Rhodesia are among the few cases in Africa where air survey³ has been used for this purpose.

In Nigeria an extensive enumeration survey of forest reserves is nearing completion and will enable stock-taking to be put in hand over a large area, but at present only a small region is under working plans. A conservator for working plans has, however, been recently appointed; a useful contribution was made in 1934 by Mr. W. D. MacGregor on the silviculture of mixed deciduous forests. In the Gold Coast important work in connexion with forest ecology has been done by the late Dr. Chipp.⁴ The enumeration of trees in selected areas has begun and 735 square miles are under administration plans. Stock-taking and exploitation have been started in Sierra Leone.

Considerable information regarding some of the French African territories is available in the form of pamphlets. A. Bertin published a work on the trees of West Africa in 1919,⁵ and the recent book on

¹ See Chap. XII, p. 767.

the trees of the Ivory Coast by Aubréville¹ is a finely illustrated work in three volumes which should prove of assistance to British forest officers; L. Bégué has also published a study of forests in the Ivory Coast.² In the Belgian Congo extensive investigations have been carried out, and the ecological studies of a Belgian Forestry Officer, Delevoy, in the Katanga have a particular value for the Forest Officers in Northern Rhodesia. Other valuable work has been carried out by de Wildeman (1920 and 1934), Vermoesen (1923), and Lebran (1935).

V. THE INTRODUCTION OF EXOTIC TREES

The early introduction of exotic trees in the Union of South Africa has already been referred to,³ and in recent years the planting of exotics has been proceeding on an ever-increasing scale. In the Rhodesias and parts of East Africa the planting of fast-growing exotic trees, particularly pines and eucalyptus, has formed an important part of the activities of the Forest Departments.⁴ The use of exotics for the formation of plantations to provide fuel and timber for towns and for the requirements of local industries has already proved a general success. In West Africa, both in the British and French colonies, the principal exotics are teak, *Cassia siamea*, *Gmelina arborea*, *Cedrela mexicana*, and *Dalbergia sissoo*. In Southern Nigeria some of the oldest teak plantations in West Africa, dating from 1912, are to be seen at Olokomeji, the growth being good; both *Cassia* and *Gmelina* flourish in West Africa in their earlier stages.

At the same time there are certain difficulties attending the growing of exotic timber. It is stated to have been the experience of Nyasaland that if exotic trees are to be successful, they must be grown on agricultural soil, which is not always available. There is, again, some doubt whether more than one or two rotations of the same exotic will be successfully obtained from the same site; in fact, fast-growing exotics may wear out the African soil more quickly than an indigenous tree grown more slowly. The experi-

¹ *La flore forestière de la Côte d'Ivoire*, 1936.

⁴ See R. S. Troup, *Exotic Forest Trees of the British Empire*, 1932.

ence of the Germans in Togo¹ shows that the reafforesting or replanting of the savannah bush may prove a far from simple operation. Time may yet show that the best way of restoring the savannah bush—and it is certainly the cheapest and easiest—is to enclose it against cultivation, grazing, and fire, and to encourage an indigenous growth of African species. It has recently been found in South Africa that some of the exotic pine plantations bring about a drier condition of soil in the neighbourhood than hitherto existed, and farmers are warned against planting such trees in large numbers in certain areas. A committee of the recent Empire Forestry Conference in South Africa studied the question of the planting of exotics in relation to the problem of conserving water supplies and preventing erosion, but it was decided that further investigation was required before any conclusion could be drawn.²

VI. TIMBERS

The largest and finest timber for export from African forests comes from the West Coast, mainly Nigeria and the Ivory Coast. Mahogany (*Khaya*) till recently was the chief species, but several others have been placed upon the market, such as *obeche* (Ivory Coast, *samba*), *iroko* and African walnut (Ivory Coast, *dibétou*). It appears that the African colonies as a whole have yet to find export markets for even as many as fifteen or twenty timbers. In Nigeria the United Africa Company have exploited some thirteen species from the Benin forests. Only 16 of the 200 species of large-sized trees growing in the high forests of the Ivory Coast have yet been found to be exploitable.³ Three of these, mahoganies, *acajou* and *acajou blanc*, and *iroko* have been continuously exploited; the remainder have only been felled intermittently in dependence on market demands and contracts. It is probable that with the experience achieved both in exploitation and in laboratory tests further marketable species will be found, and studies in colonial woods are being carried out in France with this end in view.⁴

¹ See above, p. 1006.

⁴ *Le gouvernement général de l'Afrique Occidentale Française*, Exposition Coloniale Internationale, 1931, p. 95.

The only timbers exported in any quantity from East Africa are the pencil cedar (*Juniperus procera*) to Europe and mangrove poles from the coast to Arabia and the Persian Gulf. There is a possibility of an export trade in yellow wood (*Podocarpus*), *mvule* (*Chlorophora excelsa*), and *mukushi* or Rhodesian teak (*Baikiaea plurijuga*), the latter being already exported in some quantity from the Rhodesias, while export is beginning from Tanganyika.

In the majority of areas exploitation is carried out by private agency, leases being given in which the details of working, girth limit of felling, royalty, and other conditions are laid down. The material is either exported in the log or converted before export; there is a growing tendency towards the latter method.

VII. MINOR FOREST PRODUCTS

A number of important minor products come from the African forests. Some of these are true forest products such as tans, dyes, fibres and flosses, gum arabic, resins, possible paper-pulp species, honey, wax, and medicinal drugs. Amongst minor products which pertain more to agriculture than forestry are the oil-seeds of the oil palm, shea, rubber, and the kola trees.¹

An important supply of tan stuffs from Africa is obtained from the introduced wattle, now largely grown in East Africa.² Mangroves also produce a tan; the extract is known as 'cutch' and is used for tanning fishing nets and sails. There is an export trade in mangrove bark in Tanganyika (as much as 9,000 tons in one year), and research is being undertaken into the possibilities of this trade in Nigeria, the Gambia, and Sierra Leone. There is also an old-established trade in mangrove beams (*borite*) from the Tanganyika coast to the Persian Gulf. Although not exported, certain vegetable dyes are used locally. There is a considerable dyeing industry in West Africa from indigo, with centres at Abeokuta and elsewhere in Nigeria; both wild and cultivated plants are used. Imported cotton cloths are dyed with the indigo dye, but aniline dyes are now coming into competition with it, and the question of their restriction is being considered, in the interests of the local industry. Fibres and flosses are not uncommon in the forests. Many trees and climbers yield rough cordage fibres; though

¹ See Chap. XIII, pp. 890, 911, 919.

² Ibid., p. 890.

serviceable for local purposes, these cannot compete with fibres grown as agricultural crops. Several species of the raphia palm are found in the rain forests which yield a tough fibre from the young unopened leaves.¹ *R. vinifera* and *R. gaertnerii* are found in West Africa and *R. munbuttorum* in East Tropical Africa. Coir is prepared from the husk of the coco-nut and made into mats and rough ropes. Flosses or 'silk cottons' are produced in considerable quantities from the covering of the seeds of certain species of trees, notably species of *Bombax*; the 'silk cotton' is, however, too brittle to spin. Another floss known as *kapok* is yielded by the *Ceiba pentandra*, and is to be seen in February in thick continuous masses like white snow lining the sides of the road or covering bare patches of land in dense masses. This product is being studied in central Nyasaland, in the Tanga Province of Tanganyika, and in Kenya; the seeds have been found to contain 28 per cent. of oil, and cattle cake can be made from the residue. In the Ivory Coast all isolated trees of this species in the savannah lands are marked for reservation.

The gum arabic of Africa is well known, owing to the fact that a considerable part of the world's supply comes from the Anglo-Egyptian Sudan, where it forms the most important article of trade next to cotton, and yields an annual value in recent years of about £750,000. It is an exudation from cracks or wounds in the bark of the trees, and is obtained from various species of acacia, the *verek* (*Acacia senegal*) being the most important. As a consequence of studies made in the Sudan by officers deputed from Nigeria and Tanganyika considerable progress has taken place in developing the gum trade in those territories, Northern Nigeria having exported about 1,500,000 pounds of gum in 1933. It has been suggested that co-operation between the different centres might result in better marketing schemes.² One of the difficulties is to secure a steady supply, collection as a rule being made only when crop failures have reduced the possibilities of obtaining cash from other quarters. Resins, though often confused with gums, are easily distinguishable as they are soluble only in alcohol or oil of turpen-

¹ Ibid., pp. 889-90.

² F. M. Oliphant, *The Commercial Possibilities and Development of Forests in British East Africa*, 1937, p. 19.

tine. The kinds used for making varnishes are known either as damars from the Malay States or copals from West Africa, where they are obtained from species of *Copaifera*, *Trachylobium*, and *Daniellia* species. The best quality comes from the Belgian Congo, medium quality from the Gold Coast and Sierra Leone, and the poorest from Nigeria. E. Mertens (1933) has given a full account of recent researches into the constitution of copal from the Belgian Congo, with special reference to its uses. In East Africa the chief copal tree is *Trachylobium hornemannianum*. Fossil copal known as Zanzibar animi is found chiefly in Tanganyika Territory, but exports are decreasing.

The most important indigenous rubber tree of Africa is the West African or Lagos rubber (*Funtumia elastica*) found in the ever-green forests from Uganda westwards; in addition there are various rubber vines (*Landolphia* species). An unhappy interest attaches to the sordid story of the collection of forest rubber in Africa. At one time it furnished as much as 80 per cent. of the exports of the Congo Free State, and was equally prominent in the early economic history of French Equatorial Africa.¹ Though in both cases some effort was made at a later stage to check by administrative action the grave abuses which for some years attended the grant of the rubber concessions, the system was really brought to an end by the competition of the *Hevea brasiliensis* from the Asiatic plantations. Both in Tanganyika and the Cameroons the Germans attempted the plantation of *Ceara* rubber, but this proved to be unsuitable to the climate. Some of the rubber from *Funtumia* is still collected in the French Cameroons and Equatorial Africa, but not on any considerable scale. *Hevea brasiliensis* is now cultivated by both native and European agency in Nigeria and the British Cameroons, which together exported over 4,000 tons in 1936. The Gold Coast has one plantation; Uganda has about 11,000 acres under rubber. The French Cameroons have three rubber plantations, and the Belgian Congo has 5,706 hectares under rubber. Production is cheap, and the possibilities, particularly for native cultivation, are believed to be considerable.

There are said to be openings for paper pulp production from African forests. Bamboo, the *Arundinaria alpina* of the eastern

¹ See Chap. XII, pp. 783-8.

mountains, elephant grass from Uganda and elsewhere, and some of the fast-growing softwoods of tropical Africa are suggested as possible sources of paper pulp. In South Africa attempts are being made to utilize pines, especially *Pinus patula*. None of the species, however, except possibly the South African exotic conifers, as yet shows much prospect of attaining commercial importance.

The oil palm (*Elaeis guineensis*) is indigenous to West Africa; it is rather an agricultural than a forestal product and is dealt with in Chapter XIII. The same may be said of the shea nut tree (*Butyrospermum parkii*), a native of rather dry country in West Africa now being grown in plantations. The kola tree (*Cola acuminata*) grows wild in West Africa. The nuts are eaten as a stimulant and are to-day largely obtained from plantations.¹

VIII. FOREST PESTS AND DISEASES

There is little special literature extant on either insect or fungal pests of African forests. Most of the forest entomological papers come from South Africa and deal with wood-borers, the eucalyptus snout-beetle, and insects affecting *Pinus insignis*. The staff of the Division of Plant Industry in the Union includes an entomologist, and his study of the eucalyptus snout-beetle has led to the control of this pest by biological means, except in the high veld, where conditions are unfavourable to the parasite. This is one of the few successful applications of the principle of biological control which Africa has produced. *Pinus insignis* has proved to be susceptible to diseases in parts of South Africa, but it flourishes in the Western Cape Province, where there is a good winter rainfall. The diseases of this tree have been studied in the botanical department of the University of the Witwatersrand. The gall-bug which attacks mvule (*Chlorophora excelsa*), an important timber tree of Uganda and West Africa, presents a special entomological problem. For some years it has been regarded as a serious pest; it has now been determined as *Phytolyma lata*, of the family Psyllidae, and a note on its life-history in Nigeria has been published by Mr. J. D. Kennedy.²

Indigenous trees seem little affected by parasitic fungi, but the susceptibility of introduced trees, especially *Pinus insignis*, threatens

¹ See Chap. XIII, p. 890.

² *Empire Forestry Journal*, vol. xi, 1933, pp. 37-55.

to be serious. Some pathological work has been done on agricultural and plantation crops, and in certain aspects is of direct interest to the forester; but the work on forest pathology alone is practically negligible. So far as the high forests of commercial value are concerned, however, it is doubtful whether at this stage the expense of undertaking special research into the question of pests, whether insect or fungal, would be justified.

IX. CONCLUSIONS

In dealing with the subjects which fall within the field of work of the technical departments it is not always easy to distinguish the internal problems of a department from those which have a wider aspect and come within the field of general policy. The present case presents less difficulties than some others in this respect. Technical rather than general considerations must, for example, decide the extent to which exotics are to be used in re-forestation operations, or whether it is preferable to exploit the secondary timbers for home consumption rather than to seek an external market for the few more valuable timbers.¹ It is, again, technical considerations which must determine the manner in which a forest service can make the most economic use of the establishment at its disposal. The concrete question of chief importance which arises in this respect is the extent of the staff which should be detached for the purpose of research. There are those who feel that there was at one time an undue tendency for the forest authorities in the British Empire to rely on Indian experiences, and to argue that the road to better forest administration and enhanced revenue lay through research into their forest problems, and in particular into the question of the utilization of local products. This view, however, tended to overlook the fact that the Indian Forest Administration had only approached its strong position after forty years of preliminary work, which had built up the great forest estate of India. Routine operations, such as those which concerned the protection of the forests, were adequately organized; there was a strong establishment of trained Indian officers, many capable of taking charge of independent posts; and by the time that forest research work was systematically under-

¹ See above, pp. 984 and 1007.

taken, the staff was large enough to allow of officers being specially deputed for this work, without weakening the field staff. There was nothing in Africa at the corresponding period which was comparable to the position in India. Even at the present time, staffs in most areas are barely adequate to undertake the vital work of conservation of existing forest lands. In these circumstances it would perhaps be premature to detach officers for research work of that type which is commonly known as 'long range inquiry'. Again it would seem inadvisable that the desire to secure an immediate increase in the commercial output of the forests should constitute such a preoccupation as to obscure the importance of the technical duties which the Forest Officer has to discharge in other directions. Even from the commercial aspect, certain field investigations are still needed in order to ascertain the proportion of potentially marketable species in particular forests. The work of 'stock-taking' has been undertaken only recently;¹ and in the absence of precise information regarding the stocking of the forests, and also on account of the lack of establishments, it has been difficult to produce working plans. Until forest areas are brought under the control of such plans it could scarcely be said that scientific forest management has been established.

The problem of securing closer co-ordination in the work of the forest services in different territories is not entirely one of a technical character. The Empire Forestry Conference, held every five years, establishes a useful link between officers scattered throughout Africa, and much value attaches also to the reports of the experts who from time to time are sent out by the Colonial Office on visits to the dependencies. Some value attaches also to the meetings of Forest Officers held in connexion with the Governors' Conference in East Africa.² But co-ordination of forest work does not seem to go farther than the stage of conference.³ In matters such as forestry and the closely allied subject of soil erosion,⁴ political frontiers are to a great extent arbitrary barriers; many of the problems which confront the experts on either side are identical, and it may not unreasonably be felt that common executive action is needed for their solution. It has been suggested that this pur-

³ See Chap. VI, pp. 182-5.

⁴ See Chap. XVI *passim*.

pose might best be achieved by the appointment of Inspectors-General of Forests for East and West Africa respectively. The institution of a post of this nature, dealing with a number of governments who are not federated or combined under any central administration in other aspects of their work, presents certain obvious difficulties. It is possible, however, that they could be surmounted by giving the officer (whose precise nomenclature is a matter of secondary importance) the status of adviser to the different governments; whether the Forest Officers in the different territories should be combined in an eastern and western cadre is a further question which involves points of expediency rather than of principle. Though the circumstances are not identical, some analogy for the appointment of a common supervising officer may be found in the existence of a Forestry Adviser to the Governor-General of French West Africa at Dakar. It has been suggested, again, that an African forestry publication on the lines of the *Indian Forester* or *Malayan Forester* might further be of value in promoting common action across the different administrative frontiers.

The expansion of forest work, like that of most of the technical departments of state, depends largely on the possibility of creating a cadre of African assistants, with an education and a technical training which will fit them to undertake charges of separate responsibility.¹ The extent to which these charges must continue to be of subordinate character depends on the proofs which Africans may give of their practical capacity. Up to the present no steps have been taken in British territories to create for the forest services a class equivalent to the African 'medical aids' or assistants who are now being trained for the health services.² In 1937, however, a Conference of Conservators from Uganda, Kenya, and Tanganyika made proposals for the institution of an inter-territorial forestry training school as part of the suggested higher college at Makerere.³ Experience gained of Africans in a lower range of work shows that they are very amenable to training for a forest life. There are schools for the training of subordinates of the forester and forest guard class in Uganda, Tanganyika, and

¹ See Chap. VI, pp. 255 ff.

² See Chap. XVII, pp. 1182 ff.

³ *Report on Tanganyika Territory*, op. cit., 1937, p. 152.

Nigeria; courses are also held in the Gold Coast and elsewhere. The training of this class is not yet, however, fully organized, though the matter is of some considerable importance, since, apart from the need for the possession of the necessary technical qualifications, the rangers and foresters form the link between the Forest Department and the native farmer.¹ In the circumstances in which forest work is conducted, it is not easy to exercise a close supervision over the day to day work of these subordinates, and the ability of the Forest Department to carry out its work of conservation without undue friction or disturbance of native feeling depends largely on their character and capacity.

There remains a major problem which is essentially one of general policy. There is now no lack of recognition of the necessity of extending the area of forest reservation, whether in order to preserve as a state asset the remainder of the high forest, which is peculiarly liable to destruction and degradation in Africa, or to protect the water supplies and the productivity of the soil. But both the determination of the exact extent of reservation which is required, and the method of its achievement, present problems of some complexity to the administration. There is no one formula which will establish the amount of reservation needed for protective purposes. It is not difficult to decide what forest land is required to conserve a recognizable catchment area, or to protect the sources of a particular stream. The problem becomes more complex when an administration is urged to exercise its powers in order to reserve large areas for the general conservation of the water supply of the territory or to exercise an influence on its climatic conditions. As has been seen, policy in Nigeria has for some years sought to secure a minimum reserved area of permanent forest equal to 25 per cent. of the total land area;² elsewhere 30 per cent. has been suggested as an ideal. Projects such as these may be correct in substance, but they necessarily rest on a somewhat arbitrary basis; and even if it could be demonstrated that the formula is scientifically correct for Nigeria, it would not automatically apply to Rhodesia. Nor, again, can the question of reservation be approached in the abstract. There are, no doubt,

¹ *Higher Education in East Africa*, Colonial 142, 1937, p. 108.

² See above, pp. 1000 and 1007.

areas in which a considerable extent of woodlands could be reserved without seriously reducing the lands necessary for native cultivation; but there are others (and those often in situations where reservation is most patently required) in which reservation would seriously curtail the lands now regularly cultivated. It is true that the need for a considerable proportion of the area thus occupied is due to the practice of shifting cultivation. But, as has been observed,¹ though this practice has been in the past and is even to-day undoubtedly responsible for the degradation of much high forest, its practice is often far less of a danger to the savannah or the scrub bush. It involves mischief on any serious scale only when shifting cultivation departs from its traditional methods, in order to comply with demands arising from the introduction of modern economic conditions. On the other hand, modern science has not so far been able to indicate methods, suitable for general adoption, which will be equally efficient as a means of getting the best results from a soil so subject to rapid exhaustion as that of Africa. Mixed farming has rightly been indicated as one remedy; but it is a remedy which cannot in present circumstances be applied on a very wide scale. For some time to come, therefore, calculations regarding the area required for native occupation must continue to be based on the prevalence of the practice of shifting cultivation. It is also true that when considering the areas necessary for grazing, it will not be possible entirely to neglect the African social habit which, at all events in East Africa, results in the maintenance of an uneconomic number of cattle.²

The legal position in regard to conservation presents no serious difficulty in the greater part of Africa. In the Union and Southern Rhodesia the Crown has proprietary rights over all lands over which no private title has been registered, and though the latter may constitute a very large area, there are, nevertheless, still considerable blocks of Crown land, including the native reserves. In Basutoland and Swaziland there are, it is true, difficulties, as reservation could only be effected in the former and some part of the latter by the native administrations. In Northern Rhodesia and the British East African territories, the proportion of land alienated in title is relatively small, and, except for the Mailo lands

¹ See above, p. 986.

² See Chap. XVI, pp. 1068 ff.

of Buganda,¹ or lands which come under treaty rights, such as Barotseland, the Crown has proprietary rights over all other lands, though it is subject, in the territories which have created native reserves, to the effect of ordinances which place the reserves in trust for native use. In Northern Nigeria and the Northern Territories of the Gold Coast the Crown has an over-proprietary right in all except alienated lands, but in the Southern Provinces of both territories there are legal difficulties which, as already shown, have constituted an obstacle to reservation.² The provisions of the French and Belgian laws, which give the state complete control over all 'vacant' lands,³ renders the operation of reservation, from the purely legal standpoint, one of comparative ease. The question of the reservation of forest areas, however, has two sides. It does not merely involve the withdrawal of the use of lands from those who claim that custom gives them a right of one kind or another over them, to many of whom it must appear that the operation is only designed to help people, such as the dwellers along the lower reaches of the rivers and streams, who are entirely different from those who are called upon to make the sacrifice. In actual practice the most difficult of the problems to which reservation gives rise is that of discovering a machinery for the management of the reserved lands which, while giving them the necessary protection, will do so with as little friction as possible. Only those who have experienced it can realize the depth of the resentment felt by cattle owners who see their herds, hard hit by scarcity elsewhere, excluded from pastures which are all the more tempting because they have been carefully preserved for other purposes. It is largely these considerations which have led governments to substitute for extensive schemes of state reservation, the creation of small village forests (as in particular in Nyasaland),⁴ or to the association of native authorities in the protection of the forests, as in Tanganyika or Nigeria.⁵ There are, in the former case, circumstances which especially favour the scheme, such as the fact that the scarcity of woodlands provides an induce-

¹ See Chap. XII, p. 851. The principal agreement of 1900 and the additional Forest Agreement of 1905 specially provided for the case of all forest lands other than the Mailo lands.

² See above, pp. 999-1000 and 1002.

⁴ See above, p. 994.

⁵ See above, pp. 996, 1000.

ment which is wanting where they are more extensive. But the scheme has its attractions, and other administrations will be able to judge from the experience of Nyasaland how far it can be successfully applied in their territories. Administration either by the 'village' or native authority systems is admittedly less efficient than that carried out by a state establishment. But some falling off in the standards of forest management may justifiably be faced, if the goodwill of natives is to be secured for measures designed for the preservation of their forest lands.

The fact that there are many difficulties inevitable in reservation does not relieve the administrations of the obligation to press on with it wherever they find it feasible. Their hardest task will perhaps lie in carrying the African with them, for experience elsewhere shows that the doctrine of forest conservation will encounter opposition among people who readily accept modern practice in most other respects. Rules to protect trees and forest reservations are of little use unless those who enforce them have an appreciation of their aims; the penalties are either made too light to be effective¹ or enforcement is neglected. There is, however, no reason to believe that African methods of using forest resources cannot be modified to suit modern conditions, or that simple measures of conservation cannot be practised by trained Africans with the co-operation of chiefs and their people. The need for education in the proper attitude towards forest conservation adds point to what has been said on a previous page regarding the training of an African forest staff.²

The right policy to be adopted in regard to their forest lands must always remain a matter of concern to the administrations. As the population increases, the adjusted balance between the numbers of the people and the area of land becomes upset, and the destruction of vegetation increases proportionately. It may be said, therefore, that the need for careful control and planning of the use of land increases in ratio to the density of population. The stimulation of native production also tends to extend the destruction of woodland by introducing new competition for productive land. Everything points to the need for adopting a sound forest policy from the earliest possible moment, and for making every effort to secure that its principles are understood among the African people.

CHAPTER XV

THE PROBLEM OF WATER SUPPLY¹

I. GENERAL CONDITIONS OF THE PROBLEM

THE existence of large arid or semi-arid tracts in Africa gives special importance to the possibility of utilizing irrigation from its rivers and streams or from large storage works for the protection or expansion of cultivated areas. British India can claim that 12½ per cent. of the total area sown is now irrigated;² its outlay of £115,000,000 on state irrigation undertakings has resulted in an annual production of irrigated crops valued at £77,000,000. The Punjab Province, where conditions most nearly approach those of the semi-arid zones of Africa, can point to the fact that of a total cultivated area of 26,750,000 acres, about 10,500,000 are now protected by canal irrigation, and a further 4,250,000 by wells. In Egypt, with a cultivable area estimated at about 7,250,000 acres, some 5,830,000 acres are now secured by permanent or basin irrigation from the Nile. India and Egypt are, no doubt, exceptional in the use made of irrigation; but elsewhere, as in the more arid tracts of Australia and the United States, storage or flow irrigation is becoming a factor of increasing value; in the former 3 per cent. and in the latter 5 per cent. of the cropped area are now irrigated. Experience has, however, shown that there are definite limits to the economic use of large-scale irrigation enterprises, even where the necessary physical conditions of supply, commanded area, and suitable soil are proved to exist. The interest on the initial outlay and the annual expenditure for maintenance constitute a first charge on production which can be met only from the growth of profitably marketable crops with suitable facilities for transport. That charge is of a fixed nature, and is not capable of adjustment with variations in the price of agricultural produce. Whatever, therefore, may be the indirect advantages of undertakings involving large capital outlay, they can seldom be directly remunerative where a purely subsis-

¹ Much of the material for this chapter was kindly assembled by Sir Thomas Ward, C.I.E., and Sir Arnold Musto, C.I.E.

² *Statement exhibiting the Moral and Material Progress and Condition of India, 1933-4*, p. 99.

tence economy prevails, or where a sparse population practises an extensive rather than an intensive type of cultivation, or where agriculture is only an auxiliary to stock-raising. In those circumstances the small irrigation work, availing itself of natural river flow, or of inexpensive methods of rain storage, is a more useful object for state encouragement, and it is in those conditions also that the development of the use of underground waters for the provision of drinking water for men and animals becomes of primary importance, as an agency for stabilizing cultivation or assisting the redistribution of the population.¹ The significance of these facts in African territories is best illustrated by a study of the nature of the water problems which different countries have had to face, and the steps so far taken to meet them.

II. DEVELOPMENT IN DIFFERENT TERRITORIES

(a) *The Union of South Africa*

In the more arid countries of the world irrigation has a double value, first, as a guarantee against drought, and secondly, as a normal means of securing cultivation and improving its output. In the Union of South Africa drought does not carry the same danger of famine as in Asia, where the population densities are higher; nevertheless, its recurrence has gravely retarded economic progress. The Drought Commission of 1923² assessed at £16,000,000 the direct losses in the drought of 1919; the drought of 1933 is calculated to have resulted in the loss of 8,204,392 animals,³ and the Union again suffered very severe losses between that date and 1936. The direct effects of drought, however, are seen more in the areas devoted to animal husbandry than in the agricultural districts. Measures to protect the stock-raiser belong to a somewhat different class from those intended for the protection or improvement of cultivation, and will be separately dealt with. It is proposed to deal, in the first instance, with irrigation primarily designed as an aid to agriculture.

Irrigation in Aid of Agriculture. The Union may be divided into three zones: first, that in which irrigation is unnecessary for the majority of crops, such as the coastal belt of Natal and portions

¹ See also Chap. XVI, p. 1067.

² *Report*, para. 6.

³ 'Annual Report of the Secretary for Agriculture', *Farming in South Africa*, Dec. 1934, p. 470.

of the south coast; second, that in which no crops can be grown without irrigation—namely, the greater part of the Karroo in the Cape and in the south-western Free State; and third, that in which irrigation is necessary for certain crops during portions of the year. This last zone includes the south-western corner and the eastern portions of the Cape, the north and east portions of the Orange Free State, and the greater part of the Transvaal. Here the need for irrigation arises rather from conditions attending the seasonal distribution of rainfall than from a deficiency in the total. The characteristic feature of South African meteorology is the shortage of rainfall in the months (August to October in the southern, and October to December in the northern areas) which are most critical for agriculture; it is during this period that lack of precipitation coincides with rising temperature, hot winds, and low humidity. There is indeed a certain amount of summer rainfall in the northern areas, but it is irregular and produces extensive flooding. While, however, nature has created conditions which make irrigation essential for successful agriculture in the second zone and of considerable value in the third, she has at the same time created other conditions, which limit the extent to which it can be usefully employed.

South Africa has a relatively low proportion of cultivable soils. Apart from the considerable proportion of hilly or mountainous country, much of the plateau land consists of shallow soils overlying either original rock or thick beds of secondary formations, and is of a type unsuited for the more intensive cultivation which will repay the outlay on irrigation. It was calculated by Mr. F. E. Kanthack¹ in 1922 that not more than 2 per cent. of the 302,000,000 acres of the Union proper is good or fair cultivable soil, and that only two-thirds of this, or 4,000,000 acres, would repay irrigation, if water were available. As will subsequently be seen, there are economic conditions which further reduce the area to which irrigation can usefully be applied.

The Irrigation Systems in Use. Irrigation in the Cape has for the most part been based on the flood system originally developed to meet the needs of lucerne growing on the ostrich farms. A large volume of water is led rapidly from the stream, and distributed

¹ 'Irrigation in South Africa', *The South African Geographical Journal*, Dec. 1922, p. 14.

over the entire area of irrigable land to a depth of 4 to 6 inches. In the more arid regions of the north-west Cape this system was carried a step farther, flood water being held up by embankments across flat valleys, and distributed over the series of basins thus formed. The system had the merit of low initial outlay, being estimated to cost between £2 10s. and £10 per acre irrigable. The areas physically adapted to the use of this system are, however, restricted, for the valley lands commanded by flood water are nowhere extensive, and the possibilities of flood irrigation are approaching exhaustion, with the result that recourse must in the future be had to supplies fed from storage works. In the Transvaal flood irrigation is less extensively practised, for such rain as falls during the wet season is usually sufficient for cultivation, and the valley lands are not so suitable for irrigation as those in the Cape. The primary need is for irrigation during the dry season, and the supply in the streams during the dry months is so scanty that storage in some form is essential. The greater outlay required for storage works, as compared with the flood system, has impeded the extension of irrigation in the Transvaal and the Orange Free State.

Government Irrigation Policy. Prior to union in 1910 irrigation was in the main confined to the Cape Colony. The first legislation was that of 1877, when an Act was passed providing for advances for the purpose of conserving water, and during the decade before the Boer War a number of state irrigation schemes were launched. These failed, partly because they were not carried out by specialists, and partly because of the policy of settling poor whites with no knowledge of irrigation farming on the redeemed land. Co-operative enterprise then entered the field, and was stimulated by the Cape Irrigation Act of 1906. From 1906 to 1914 was a period of great activity and many irrigation districts were proclaimed and irrigation boards formed to which large sums of public money were loaned. The irrigation works, as has been shown above, were comparatively cheap, and the rates charged by the boards were low, but the capital cost of bringing the land under cultivation was heavy, and this the farmers had to meet themselves. They were seldom able, therefore, to manage more than twelve acres under irrigation, though the average holding was far larger, and was all liable to irrigation

rates once an irrigation district had been proclaimed. Owners with excessive areas of rateable land which they had not been able to develop within the period of grace allowed by the Act found themselves unable to pay even low irrigation rates. The collapse of the ostrich feather boom aggravated these difficulties. When the demand for lucerne had gone, farmers had to turn to other crops, which all need a more regular water supply, with the result that the flood irrigation systems had to be changed into perennial systems. Large and expensive storage works became necessary, so that the capital burden on irrigable land, heavy before, became in many cases unbearable, and there were many failures and continuous pressure for the write-off of loans. This collapse could have been avoided if the granting of a government loan to an irrigation board had been made conditional on all undeveloped irrigable land being sold to the government at prairie value for settlement schemes, but the courage to adopt such a policy was lacking at the time.

In 1926 the Union Government instituted an Irrigation Commission, which was charged primarily with the task of scrutinizing projects, and the co-ordination of the operations of the different agencies concerned in irrigation. In 1934, the Act¹ authorizing the extension of the Vaal river scheme made a significant advance in its assertion of state rights to the water of the river. Riparian owners had acquired rights under common law, but in order to secure the most beneficial use of the water in the general interests of the community, the government found it necessary, while protecting rights of user already acquired, to limit the right of the riparian owner to the use of one-fifth of a cusec of water for every mile of frontage. The problem created by the claim of riparian owners to common law rights in water is one which, as will be seen, has arisen also in Kenya and Tanganyika. In further legislation,² the government provided for a measure of expropriation of lands required for settlement under large national schemes; it prescribed the Water Board instead of a court of arbitration as the tribunal for deciding claims.

Up to 1934 government itself had been responsible for a considerable number of schemes, but the Hartebeestpoort and Oli-

¹ Act 38 of 1934.

² Act 46 of 1934.

phants River Works alone involved large expenditure.¹ In 1934 it sanctioned the Vaal Hartz scheme, an undertaking of greater magnitude. The site of the work was chosen in consultation with the Rand Water Board, which contributed to the cost. The big reservoir on the Vaal is of great value to the Witwatersrand, and for the first time in the history of South African water law, large quantities of water have been made available for industries.

The commanded area on the Vaal project is calculated roughly at 103,000 acres, but it is not easy from the published figures to judge how far its value as an irrigation project will justify the estimated expenditure of £4,000,000. Complete figures of the area under irrigation in the Union are not available, but an estimate published for 1934-5² put the total at 352,943 acres. Of the area cropped under irrigation, 41 per cent. was under cereals, 23 per cent. under lucerne, 7.5 per cent. under citrus, and 8.5 per cent. under vines and tobacco. Up to 1935 the state had spent about £11,000,000 on irrigation, of which some £5,861,000 represents loans and advances, and the remainder direct expenditure by the state. To the latter must be added some £4,000,000, to which the state is committed on the Vaal Hartz and other schemes. Of the loans and advances only £665,000 had been repaid, and £3,541,000 had already been written off. It is estimated that in all a total of £4,500,000, or 76 per cent. of the whole amount advanced, may have to be written off as irrecoverable. The aid given on this account must be regarded as a part of the subvention accorded to agriculture. The Union has not yet published any systematic account of its irrigation work, giving such necessary information as commanded and cultivable areas, actual crops grown, the average 'duty' per unit of water, or the return to capital outlay. No accurate comparison is therefore at present possible with the efficiency attained by similar schemes elsewhere, but it is stated that steps are being taken to compile such complete records.

The Potential Development of Irrigation. It has been shown that the area having soil suitable for irrigation is estimated at not more

¹ See *Report of the Director of Irrigation for 1934-35*, p. 43, for a schedule of state irrigation works and their cost.

² *Ibid.*, pp. 26-7.

than 4,000,000 acres. The study of the relationship of rainfall and run-off in South Africa involves problems of some complexity; it was, however, calculated in 1922 that, on the basis of run-off, water might be considered to be available for not more than 3,000,000 acres. Economic conditions would, however, seem to impose a further limitation on the possibility of irrigating any large proportion of this area. The cost of constructing storage supplies has hitherto varied from a minimum of £14 to £160 an acre rateable, from which it would appear that the cost per irrigable acre must be considerably higher. The cost of the larger-flow irrigation schemes in India is not strictly comparable, but it may be noted that the recent Sind Barrage scheme showed a capital cost of about £3 an acre annually irrigable; a more relevant comparison could be made with some of the larger Indian storage schemes, such as that at Bhatghar in Bombay, with an annual irrigation of 80,000 acres, and a capital cost of £5 10s. per acre irrigated annually. This was erected at pre-war prices; an extension of the scheme with a more expensive form of dam will give over its enlarged area a capital cost of £20 17s. 6d. per acre irrigated annually. From such figures as are available the cost of the Vaal Hartz scheme will be about £40 per rateable acre, and of course a much larger sum per irrigable acre. It may be noted that water storage in South Africa is made still more costly by the high percentage of evaporation and the rapid silting up of the reservoirs,¹ which are fed by the *débris*-laden run-off from barren mountain ranges; the storage capacity decreases within a comparatively small number of generations unless expensive schemes of head-water reafforestation are undertaken. Thus the cost of constructing irrigation works, together with the cost of preparing the land for irrigation, is generally so great in South Africa that land potentially irrigable has little greater value than similar non-irrigable land, and there is no justification for selling at £10 or more per acre land with an unimproved value of £2 per acre, merely on the ground that it can be irrigated; before irrigation a further outlay of some £25 per acre may have to be incurred. Unless irrigated land is carrying high-grade crops which command a ready market, the farmer cannot afford a total capital outlay of

¹ See Chap. XVI, p. 1060.

much more than £10 per acre, especially as he runs many risks in South Africa besides that of water shortage. It will only be possible to undertake future schemes if the government is prepared to bear a considerable share of the initial cost of providing storage water and of developing the plots up to the productive stage. It was no doubt considerations of this character that led the Director of Irrigation in the Union to state in 1930 that the maximum area which could be economically irrigated did not exceed 1,000,000 acres.

Irrigation for Stock-Raising Purposes. It is reasonable to feel that the most profitable use of irrigation lies in projects which will provide greater security to the stock-raiser. It was in this direction, indeed, that the recommendations of the Drought Commission of 1923 mainly tended. There is a vast extent of good grazing veld, but its stock-carrying capacity is reduced by irregularity of rainfall, the uncertainty of drinking-water supply, and the absence of facilities for forming reserves of fodder. The losses of stock-raisers in times of drought are, as has been shown, immense; the figures available also seem to point to high mortality even in normal years. There is justification for the view, which has been strongly held in some quarters, that such limited means of irrigation as the rivers and streams can supply would be better devoted to the growth of reserves of fodder, save perhaps when utilized for crops of exceptional value, such as citrus. Irrigation would thus perform a valuable function in stabilizing the animal industry, and the insurance afforded against the recurring losses of stock-raisers might reasonably be held to compensate the state for bearing a part of the cost involved. The possibilities of this use of irrigation have not yet been fully explored, but if further investigation appears to justify expenditure in this direction, then it would seem that available supplies of water would have to be utilized in small schemes, scattered over as wide an area as possible, rather than in major projects. A considerable part of the assistance to stock-raisers in the Union will, however, continue to come as at present from the use of subsoil water or the provision of small dams for storing rainwater. Indeed, the development of South Africa already owes more to the utilization of underground than of surface water, and there is a measure of truth in the claim of Dr. A.

du Toit' that 'more has been achieved towards the general development of the country from the comparatively few thousands of pounds spent annually upon state boring, than from all the millions expended upon large diversion and storage schemes'.

The Use of Underground Water Supplies. The Government of the Cape first began boring by state agency in 1904, and a boring branch of the Irrigation Department was created in 1910. Under the present system the state supplies the machinery and establishment, while fuel and labour are provided by the farmer. The average cost to the latter has varied from 16s. 2d. per foot drilled in 1919-20 to 13s. 3d. in 1933-4; the average depth of boreholes in the Union is 150 feet, and in South-West Africa about 260 feet. In the Union reserves the expenditure is undertaken by the Native Affairs Department, and of late years a commendable expansion of boring has taken place. The experience gained by the Irrigation Department and the surveys made by the Department of Geology now enable drilling to be undertaken in a systematic way with knowledge of underground conditions. It would appear that there is commonly no actual 'water table': the supply in all cases is maintained by infiltration through pervious strata from annual rainfall, and is usually of local and not far travelled origin. The character of the subsoil beds rather than the amount of rainfall seems, therefore, to determine the amount of water available; there is, for instance, less trouble in obtaining water in the semi-arid Karroo than in the Transvaal or Natal with treble the rainfall.² The boring branch from 1903 up to March 31, 1935, completed 19,473 boreholes in the Union. Observations show that the average supply given by each borehole is between one-thirtieth and one-fortieth of a cubic foot per second, or sufficient at the most for only about 7 or 8 acres of mixed crops; it is therefore of little use for agricultural purposes, but of great value for providing drinking water and for garden use. Artesian supplies have been found only in the Uitenhage district of the Union and in Namaqualand and east of Marienthal in South-

¹ A. L. du Toit, 'Borehole Water Supplies in the Union of South Africa', *Proceedings of the South African Society of Civil Engineers*, vol. xxvi, 1928, p. 74.

² A. L. du Toit, *Geology of South Africa*, 1926, p. 420.

West Africa: they may prove to be of some value for small irrigation schemes.

Small Dams. The value of the rainwater dam lies not only in its provision of an emergency water supply, but in assisting to prevent erosion. The embanking of slopes helps to prevent 'sluiting'; and an increase of drinking places, by allowing the substitution of fenced paddocks for the 'kraaling' and herding of stock, reduces the trampling which is one of the chief causes of erosion.¹ Up to a recent date this fact was not sufficiently appreciated by farmers, but the Union Government has now given substantial stimulus to the making of dams, by action taken as part of its anti-erosion programme. Owners of farms who build dams can either recover 25 per cent. of the cost, or receive a loan covering the expenditure on the dam, subject to repayment within thirty years at 3½ per cent. Special terms are given to farmers who construct dams with European labour.² It has been contended with some justice that the expenditure on these objects constitutes a legitimate use of the windfall from the price of gold; it is the most effective insurance which the Union can make against the results of a possible decrease in the profits of the mining industry. A certain number of dams have been made by the Native Affairs Department in the native reserves, though a great deal more work of this nature remains to be done; in the Transkeian Territories the General Council has built a considerable number, some 250 having been constructed in the Umtata District alone.

(b) *South-West Africa*

In South-West Africa irrigation is practically non-existent, and the natural water resources of the territory offer scanty facilities for its development. With the exception of the Orange river in the south, the Okavango and Kunene rivers in the north, and the Zambesi and Kwando rivers in the Caprivizipfel, all the streams in South-West Africa flow intermittently even in the rainy season, and in the east many of the rivers sink out of sight in the Kalahari desert. Waters coming from Portuguese territory inundate Ovamboland, but owing to the silting up of channels in the Kunene river in Portuguese territory, the supply is decreasing. An inter-

¹ See Chap. XVI, pp. 1067, 1080.

² *Ibid.*, pp. 1082 ff.

national commission reached an agreement in 1926, allowing the Government of South-West Africa to clear channels upstream and to construct a dam about 3 kilometres above the Rua Cana Falls. This project was, however, abandoned owing to the high cost. Meanwhile the delimitation of the international boundaries has resulted in numbers of the Ovakuanyama tribe being in Portuguese territory; most of these are anxious to reunite in South-West Africa, but are unable to do so owing to lack of water supplies. Boring operations have proved a failure and other ways out of this difficulty are being explored. The situation was relieved to a great extent by the heavy rains of 1934 and by floods in 1936. Wells have been successfully sunk in the Eastern Ukuanyama, from which extension work eastwards is being undertaken, allowing settlement in a strip of country twenty-five miles long.

When the native reserves were marked out 124 boreholes were put down and £22,000 was set aside for this purpose, apart from Trust funds. During the period 1927-35 the boring branch of the Union Irrigation Department had completed 1,457 boreholes, but many of these were on European farms or in the Police Zone. In 1936 it was stated that, as much of the work in the reserves falls to the aged and infirm, owing to the absence of able-bodied men at work, the hand-pumps provided for the Hottentots have proved unsatisfactory. Considerable work remains to be done in sinking wells and repairing dams both in the reserves within the Police Zone and elsewhere.

(c) *Bechuanaland Protectorate*

The history of hydrography in the Bechuanaland Protectorate has an interest of its own. When Livingstone first visited the Victoria Falls he was impressed with the striking evidence which they offered of river erosion, and formed the opinion that there had once existed a vast lake in the northern Kalahari, the waters of which had been drained away by the Zambesi through a great rent in the earth which determined the Victoria Falls. Seventy years later his theory was revived in a modified form by the late Professor Schwarz,¹ who suggested that the Zambesi, by capturing

¹ *The Kalahari or Thirstland Redemption*, 1920. See E. B. Worthington, *op. cit.*, chap. iv.

the waters of the Linyanti (Chobe) river, had drained away the waters of the Okavango river system and incidentally those of Lake N'gami. He held that the loss of these inland bodies of water was responsible for the aridity of the central parts of southern Africa, and anticipated that if the lost lakes could be restored, there would be an increase of rainfall over so vast an area that danger from drought in South Africa would be a thing of the past. Scientists gave no support to Professor Schwarz's theories, and little of the public interest which they once attracted now survives. In 1925 a mission dispatched by the Union Government, while finally rejecting the views of the professor, proposed that an area of 125,000 acres within the Matabele depression might be irrigated from the Linyanti river at a cost of about £5 an acre, and that about 30,000 to 40,000 acres on the eastern part of the floor of Lake N'gami might be developed at a cost of about £6 an acre.¹ The schemes were not carried out, however, in view of the scarcity of population in the native reserves, the difficulties of transport and lack of markets, and the existence of tsetse-fly and endemic malaria in part of the delta area.

The immediate need of the Bechuanaland Protectorate is less for agricultural irrigation than for the provision of an adequate supply of drinking water; it is indeed clear that the serious lack of water for human beings as well as for cattle is one of the chief obstacles to the development of the country.² In the south is the Kalahari desert; in the north the whole of N'gamiland to Lake N'gami in the south and along the Botletle river as far as Rakops to the west, is dependent on the flow of the Okavango river after its waters have spread through vast areas of swamps. Since 1925, which was the last occasion when water found its way along the Botletle river and to Lake N'gami, the channels through the swamps have become more and more restricted by silting and vegetable growth, and in 1932 work was started to clear and remove obstructions along the main channels. During 1933 and 1934 grants of £4,000 were made for this purpose from the Colonial Development Fund. Some success was attained, but the work seemed to justify a larger expenditure, and a further grant of £8,000 has now been made from the

¹ *Report of the Kalahari Reconnaissance, 1925.*

² *Report on the Financial and Economic Position of Bechuanaland, Cmd. 4368, 1933, p. 110.*

fund to enable clearing operations to be continued and a comprehensive survey to be undertaken. There arc, it may be noted, those who would prefer to drain the Okavango swamps and use the waters to grow rice and other crops; the cheapness of such a scheme would, they believe, justify it in spite of the difficulties of sparse population and lack of markets which would have to be faced. This matter is one which may repay further investigation; meanwhile it is clear that the question of water supply in other parts of the protectorate needs serious attention. This need is best met by a development of the supplies obtainable from underground sources or from the construction of small storage dams. Up to 1928 some boring work was done by the natives themselves, but on a very small scale. In 1929 the administration endeavoured to improve the position, but very little could be accomplished owing to lack of funds, and up to 1933 government assistance had extended only to the sinking of thirty-six boreholes. Nineteen of these were failures, mainly because efforts had to be directed to finding supplies at settlements and other places known to be unpromising geologically. Sir Alan Pim's Report of 1933¹ on the protectorate emphasized the need for a more energetic programme of boring, preceded by a systematic survey. The geological conditions are sufficiently similar to those of the Union and South-West Africa to allow geologists to make a reasonable forecast of the average depth and quantity of water likely to be obtained by drilling. Several schemes for a gradual and systematic programme of water development were prepared, and in August 1935 a grant of £25,000 was received from the Colonial Development Fund. Some time elapsed before plant and equipment and final surveys were completed, but an organized start was made in 1936. By April 1937 twenty-five boreholes and three wells had been sunk, and four other boreholes and seven other wells were in course of construction, while a dam conserving 370,000,000 gallons of water had been completed and work started on several small-surface contour dams. During the progress of this work a scheme for further development was prepared, and a fresh grant of £144,400 has been made from the Colonial Development Fund to cover the next four years.

¹ *Report on the Financial and Economic Position of Bechuanaland*, Cmd. 4368, 1933, p. 110.

(d) Basutoland and Swaziland

In Basutoland the chief danger is not drought but soil erosion.¹ The Colonial Development Fund has recently provided a loan of £160,000 for anti-erosion works² designed to ensure the even distribution of storm water and its conservation. There is also a need for small irrigation works to utilize water from storage dams and perennial streams in the cultivation of crops and fodder reserves; such works would incidentally supplement the main anti-soil erosion scheme. The Colonial Development Advisory Committee have expressed their readiness to consider a grant for this purpose when the anti-erosion work has progressed further, and the possibilities of such small irrigation works have been adequately surveyed. The Basutoland Government is now making provision in its estimates for an annual sum for the safeguarding and improvement of village drinking-water supplies.

Swaziland, which contains in proportion to its size an unusual number of streams and rivers, would at first sight appear to be well suited for irrigation. Of the three physical sections into which it is divided, the high veld offers few possibilities, but various schemes have at different times been investigated in the middle and low veld areas. In 1927 the Union Irrigation Department made an inquiry into proposals for utilizing the water of six rivers—the Komati, the Usutu proper, the Little Usutu, the Black and White Mbuluzi, and the Ingwavuma.³ The survey was of a preliminary nature, and confined mainly to engineering details. The scheme for the White Mbuluzi was considered impracticable; of the others that on the Little Usutu, in the low veld, seemed to promise some success. It is, however, in Sir Alan Pim's opinion doubtful if it would repay outlay unless developed under conditions of high-priced cropping. Some attempt has been already made at irrigation from the Ingwavuma, but this has so far been rendered unsuccessful by the irregular flow of the river. The scheme considered for the lower Komati was devised mainly in the interests of irrigation in the Union beyond the Swaziland border. It was rejected on account of the danger of alkali, but further

¹ *Report on the Financial and Economic Position of Basutoland*, Cmd. 4907, 1935, p. 143.

² See Chap. XVI, p. 1084.

³ *Report on the Financial and Economic Situation of Swaziland*, Cmd. 4114, 1932, p. 98.

surveys would seem to be justified, for the area contains excellent veld land. The Usutu proper appears to offer possibilities of irrigation near the Lebombo range at Big Bend, but qualified opinion holds that, before embarking on any work involving large capital outlay, some practical experience is required of irrigation carried out in Swaziland conditions, as insufficient material exists on which to base final estimates of the productive capacity of such works. The British Government has not so far made provision for such schemes: if finance were provided for small individual or community projects, they might afford the data necessary to estimate the possibilities of larger undertakings.

There is an urgent need for the construction of small rainfall dams, which have already been tried with success in Swaziland, and the methods adopted by Transkei and other Union reserves might well be followed. An experienced engineer employed by the Union Government has confirmed this view in a recent survey. Boreholes have generally proved a failure in Swaziland.

(e) *The Rhodesias*

No detailed survey of irrigation facilities has been undertaken either in Southern or Northern Rhodesia, though a reconnaissance party was at work in the former area until it was discontinued as an economy measure in 1931. It would not appear that the economic or agricultural conditions in either area are such as to promise success to any scheme involving large capital outlay. In Southern Rhodesia two small schemes in the Umtali District have been financed from loan funds, and a dam on the Mazoe estate, with a storage capacity of 5,000,000 gallons, estimated to command 6,000 acres of land, has been constructed by the British South Africa Company for protection of its citrus plantations. For the most part, however, irrigation must be viewed in the light of assistance to stock-raising, for which the small work, supplying sufficient water for the cultivation of fodder reserves, offers most advantage. The movement which is now taking place towards mixed farming will no doubt stimulate the demand for such schemes. So far projects have been prepared which are estimated to command 63,000 acres; the area now under irrigation is stated to be 20,000 acres.

In certain of the Southern Rhodesian districts, as, for instance, in the more arid areas of western Matabeleland, there is a pressing need for the development of underground supplies for drinking purposes. The state maintains an engineering and well-boring establishment which carries out drilling for farmers on terms similar to those in force in the Union: the cost to the farmer is given at 17s. to 18s. per foot drilled. Figures of the total number of boreholes made do not seem to have been published, but of late years an appreciable increase in activity is reported in the native reserves and purchase areas; by no means all of these undertakings can, however, be said to have been successful.¹ Geophysical prospecting, which has been found greatly superior to the method of selecting sites by surface indications, is being extended, and the administration intends to concentrate upon constructing small storage works, each serving not more than 400 head of cattle.

In Northern Rhodesia official reports have spoken of the need for boring operations in the drier areas. In the native reserves some wells have been sunk and dams constructed, but on the whole the work has been spasmodic and often unsatisfactory.² The total estimated expenditure from loan funds on the schemes is £15,667, apart from smaller amounts from native reserve funds and under the tax relief schemes. In the Southern Province a water-development staff is engaged on surveys and on the supervision of works financed from native reserve funds. Operations in the copperbelt area have given indications of the existence of artesian supplies, which would seem to warrant further investigation.

(f) *Nyasaland*

The question of water supply has received much attention in Nyasaland, where the Geological Survey Department has since 1923 been in charge not only of the surveys necessary, but of the drilling operations.³ The mean annual rainfall of Nyasaland (between 30 and 45 inches) gives it some advantage over areas lying farther south; but the restriction of the rainfall to four

¹ *Report on the Financial and Economic Position of Northern Rhodesia*, 1938, para. 141.

² *Ibid.*, para. 151.

³ Geological Survey Department; *Water Supply Investigation (Report No. 4)*, 1934.

months of the year creates problems in connexion with domestic water supply, which have an important bearing on schemes for the redistribution of population in the more congested areas. The population density for the whole territory is 34·6 per square mile, which is higher than Northern Rhodesia (3·2) or Tanganyika (13·7); and in addition a large proportion is confined to the vicinity of the permanent water of Lake Nyasa or of rivers such as the Shire. In 1930 a grant of £40,180 was made from the Colonial Development Fund. This has resulted in the production of valuable physical maps of Nyasaland with special reference to the existence of water supplies, and the preparation by Dr. F. Dixey of a *Handbook of Water Supply*.¹ By 1935 some 256 wells and boreholes had been constructed, and 481 square miles of land were in process of being opened up by the extension of drinking-water supplies. A further grant of £44,250 was made in 1936 for the continuation of the work during the next five years.

(g) Kenya

The possibilities of irrigation in Kenya received some attention in an administrative survey made in 1911, but first came under serious examination in 1925 when the Director of Irrigation in the Union, Mr. A. D. Lewis,² was delegated to visit the colony. His inquiry was directed to the question of the supply of water for stock rather than to irrigation for agricultural purposes; but he was able to indicate that the Tana river offered possibilities for irrigation which might repay further examination. This was not undertaken till 1934, when Messrs. D. G. Harris and H. C. Sampson³ made an expert reconnaissance of the Tana area. They showed that physical and health conditions made it inadvisable to proceed further with the scheme in which the Kenya Government had itself been interested—namely, the development of the lower or deltaic Tana—nor did it appear that the middle Tana was likely to yield a return proportionate to the heavy outlay on head-works involved. A canal on the upper Tana was shown to be technically feasible, with a capital cost of about £2,000,000. But

¹ F. Dixey, *A Practical Handbook of Water Supply*, 1931.

² *Report on Irrigation, Water Supplies for Stock, Water Law, &c., in Kenya*, 1925.

³ *Irrigation Report of the Tana River Expedition*, 1934.

in their view it could be recommended in the first instance mainly as a protection against famine, and as some solution of the overstocking problem, rather than as a productive work; it seemed likely to prove self-supporting only after a considerable period had elapsed. The success of such a scheme does not depend only on engineering conditions; it involves a complexity of novel problems connected with the reaction of the soil to irrigation, the introduction of intensive cultivation, and colonization by native settlers. They therefore recommended that experience should be sought in the development of some smaller scheme, and instanced the Perkerra river in the Kamasia reserve as suitable for the purpose.

This project has two sections, of which the first is roughly estimated to command about 3,000 and the second about 5,000 acres. The scheme would have its own value in the reserve, where scarcity relief has to be given annually, but its character would be that of a protective rather than of a productive work. As a result of this report, the Kenya Government is now proceeding with the detailed survey of the Perkerra scheme. It has been of great advantage to Kenya to have before it an expert view of the economic conditions which must regulate development by river irrigation. It may be noted that there is a small native irrigation system in the West Suk district of the Rift valley, similar to that of the Chaga on Kilimanjaro, though less skilfully organized.

The supply of water for drinking purposes, particularly in some of the native reserves, remains a matter of the first importance. The report of Mr. Lewis had pointed out that about 65,000 square miles of the territory lie in a rainfall area of between 20 and 30 inches, in which the provision of water supplies for stock is an urgent necessity; 93,000 square miles lie in an area of less than 20 inches of rainfall, and with the exception of a few areas held by tribes along the Tana, Sabaki, and Uaso rivers this is almost uninhabited. Drilling was started on a small scale by the government in 1926, and the technical aspects of the work were reported on by Mr. A. Beeby Thompson¹ in 1929. The results of the experience gained between 1926 and 1932 formed the subject of a further report by Mr. H. C. Sikes in 1934.² At that date

¹ *Kenya Water Problems*, 1929.

² *The Underground Water Resources of Kenya Colony*, 1934.

some 174 boreholes had been sunk, at an average depth of 251 feet, of which 63 were unsuccessful. The sum expended by government before the operations were closed down as an economy measure in 1931-2 amounted to £91,125; the charges for the hiring of drills by farmers were based on those prevailing in South Africa, but circumstances, including the early closure of operations, tended to make the average cost higher than in the Union. These operations have now been renewed in certain of the reserves, with the aid of a grant of £42,000 made in 1936 from the Colonial Development Fund.

As in Tanganyika the question of water rights has involved much discussion. The first Ordinance on this subject was 29 of 1929, and in 1936 an amending Water Ordinance was passed in order to regulate the chaotic position previously existing. Hitherto, the use of water supplies had been regulated by the issue of permits conveying no legal rights, but the need for a legal definition of rights is clear. About 1,500 permits had been issued under the old procedure; the recent ordinance will involve a survey and allocation of rights. The problem has come to the front mainly owing to difficulties encountered by settlers, but in the course of the survey native rights will also have to be taken into account.

(h) *Tanganyika*

The Germans were attracted by the potentialities for irrigation offered by the Tanganyika river systems, and in 1909-10 they examined a scheme for the canalization of the valley of the Kilombero, a tributary of the Rufiji.¹ The available information suggests, however, that this area is not suitable for development by irrigation. The valley is subject to flood conditions and malaria would create a serious health problem. It seems suitable for the production both of rice and cotton on flood lands, and under a scheme organized by the Liverpool Uganda Company produced about 2,000 bales of cotton in 1936. Its future development depends on the possibility of improving the general conditions by extension of communications and of health measures; the problem is not actually one of irrigation. An interesting native irrigation

¹ C. Gillman, *Journal of the Royal Geographical Society*, lxi, 1927, pp. 101-21; A. M. Telford, *Report on the Rufiji and Kilombero Rivers*, 1929.

system exists on Mounts Meru and Kilimanjaro. Its precise history is unknown, but a survey¹ made by Sir Edmund Teale and Mr. C. Gillman in 1934-5 showed that though the method used is primitive the channels are well graded and are led for many miles over difficult ground; the distribution is regulated by long-established native law and custom. It would not, however, appear practicable to effect any great extension of the system by conservation of flood waters on the mountain, and the problem presented is that of securing a more economical use of the existing supplies, which are somewhat wastefully used. The report suggested that if irrigation was to be extended, a possible site existed at Nyumba Ya Mawe on the Pagani river, but so far no detailed examination has been made of this project, which is of very doubtful value.

The needs of Tanganyika, however, like those of other East African territories, seem to lie rather in the development of drinking-water supplies for men and cattle than in the construction of irrigation works. Even where river water is available most of the soils commanded are residual and liable to become saline unless costly drainage is resorted to. On the other hand the valuable study of population distribution made by Mr. C. Gillman² shows that two-thirds of the residents of Tanganyika are concentrated on one-tenth of the area, which alone possesses enough water to support them. Many of these 'oases' are approaching congestion. The provision of drinking water becomes of the highest importance in dealing with problems such as that of the prevention of wastage of pasture, and consequent erosion, by the adoption of a system of rotational grazing, or that of the transfer of the population from areas affected by tsetse. So far little progress has been made in drilling boreholes, and there has been a high proportion of failures due to the occurrence of brackish water. It has indeed been suggested that the geological conditions on the whole are less favourable for subsoil water development than in Kenya. In 1931 field work was begun on a scheme of water boring, for which a loan of £10,000 from the Colonial

¹ *Report on the Investigation of the proper Control of Water and the Reorganization of Water Boards in the Northern Provinces of Tanganyika Territory, November to December, 1934.*

² *American Geographical Review*, July 1936. See also *Report to the League of Nations on Tanganyika Territory, 1935.*

Development Fund was approved in February 1930, and the Geological Department, which is now in charge of this work, had between 1931 and 1934 completed fifty-two boreholes at an average cost varying from £280 in 1931 to £139 in 1933. Sixty-nine per cent. of the sites chosen for boring have produced water in adequate quantities. In 1937 the Colonial Development Fund provided £40,430 for a hydrographic survey and reconnaissance of water resources. The majority of the boreholes have been drilled for the sisal industry and the native administrations and railway. In the Lake Province native administrations have provided machine pumps and windmill pumps at boreholes, and have constructed dams, in association with boreholes, springs, or natural catchment areas.

The need for regulation of the native system on Mount Kilimanjaro and of the supplies from watercourses elsewhere, especially those in areas which have been the subject of land grants, has directed attention to the need for amending the law relating to water rights. The present Natural Water Supply Ordinance¹ constituting local water boards is clearly inadequate in the absence of any law defining rights in water. Experience elsewhere seems to suggest that a solution can only be found in claiming for the state the right to control all natural water supplies; it is dangerous to allow a law of water rights to grow up based on English common law.² Mr. F. E. Kanthack, the consulting engineer recently called in by the Tanganyika Government has reported in the same sense.³ The government is now initiating measures for a complete hydrographic survey of Tanganyika, and a grant of £57,570 has recently been made by the Colonial Development Fund towards this survey and for accompanying irrigation experiments and forestry work.

(i) *Uganda*

The survey of water-supply conditions in Uganda by its Director of Geology, Mr. E. J. Wayland, points to the importance of preventing the process of silting up which is overtaking a number of the lakes and rivers. This problem requires further investigation;

¹ *Laws*, cap. 75.

³ F. E. Kanthack; *Report on the Control of Natural Waters of Tanganyika*, 1938.

meanwhile the immediate need is for improved domestic water supplies. Here the needs are local rather than general. Save in the north-east the rainfall averages from 35 to 45 inches, but there are localities where local scarcity prevails owing to seasonal fluctuations in the rainfall. For some years the Geological Department had urged that a hydrographic survey should be undertaken accompanied by experiments in drilling, and in 1930 a start was made with a small boring equipment. By 1935 some seventy-seven boreholes had been drilled of which only forty-six were successful, which seems to bear out the geologist's forecast that large stores of easily-tapped underground water were not to be expected in the protectorate. It is possible that a solution may have to be sought in a better-organized development of rainfall storage by means of dams and tanks.

(j) *Nigeria and the Gold Coast*

In the Southern Provinces of Nigeria the development of water resources is not so urgently required in the interests of agriculture or animal husbandry as in most parts of East Africa; the chief need is for an improved domestic supply in the interests of health. This has in particular been felt in Owerri Province, where in spite of high rainfall there has sometimes been serious water shortage, and the Geological Department has started a well-sinking programme after a geophysical survey for underground water. In the Northern Provinces, where the rainless seven months are accompanied by the drying harmattan, the water supply is of vital importance. The extension of the system of mixed farming, to which agricultural authorities are looking for the expansion of production,¹ depends largely on the water supply; and if water were more readily available it would be easier to redistribute the population in the congested areas of the northern emirates. No schemes for the use of river water on any considerable scale have yet been developed, though use has been made of storage on a small scale at Sokoto.

The possibilities of an extended use of underground supplies were investigated by Mr. Beeby Thompson² in 1933 in the course of a general survey of the water problem of Nigeria. Geological

¹ See Chap. XIII, p. 963.

² *Report on the Water Problems of Nigeria*, 1933.

conditions appear on the whole favourable, and Fulani well-sinkers had already shown much skill in digging wells in some of the northern emirates, though they seldom possessed the technical ability to succeed when any thickness of dry beds had to be penetrated. During the years 1929-33 the Geological Department had sunk some 268 open wells at the relatively low cost of about 10s. a foot. Mr. Beeby Thompson considered that further progress required a better drilling organization than had hitherto been available to the Geological Department; in many parts subsoil water could not be reached by hand-dug shafts. Drive tube wells could be usefully employed in the river valleys and existing shafts improved by boring deeper into the water-bearing beds, suitably screened casing being inserted on the method employed with success in certain areas of Northern India.

Since the date of Mr. Beeby Thompson's inquiry the number of open wells constructed by the Geological Department has steadily progressed, and the total number at the end of 1936 was 941. An examination made in 1934 of the Lake Chad area, which may be defined as the country running north of a line drawn through Bauchi, Potiskum, and Maiduguri, showed that it presented special opportunities for drilling in its promise of sub-artesian supplies.¹ Funds were in 1935 provided for the extension of the water work of the Geological Department, covering a five years' programme at a cost of £33,500, and the drilling equipment necessary to pursue boring operations has now been furnished. The department has made a complete survey of underground supplies in the northern emirates and has made a considerable use of the geophysical method in its survey. The actual cost of making open wells is borne by the native administrations. It may be noted that experiments made in 1933 in lifting water from open wells show that supplies (save perhaps in the river valleys) are unlikely to be sufficient for irrigating crops on any useful scale, as the depth from which the water has to be lifted is too great; the open wells have not so far been found to give a supply at all comparable with those used for irrigation in Northern India, where the average well worked by a Persian wheel is estimated to yield about 5,625 gallons an hour. The

¹ C. Raeburn and B. Jones, *The Chad Basin: Geology and Water Supply*, 1934.

main benefit appears to lie in the assistance given to mixed farming and the stabilization of agricultural conditions.

In the Northern Territories of the Gold Coast the water problem resembles that of Northern Nigeria, and the development of agricultural production would seem to depend mainly on the expansion of drinking-water supplies. A survey of the area has been made by an officer of the Geological Department; the number of new wells considered necessary in the Northern Territories and in Togoland under British mandate is 2,001, and the number of dams 56, and it was recommended that £2,500 should also be provided for cleaning and repairing existing ponds and water holes.¹ A Water Department has now been formed and expenditure of £7,000 was provided for 1937; the programme of work will probably extend over six years. There exists near Pong Tamale an interesting series of underground water reservoirs (belligers) excavated by natives in the impervious strata below a hard layer of laterite concretions; assistance given in their clearing and maintenance would be of considerable benefit to the local population.

(k) *The French Territories*

The French West African authorities, in dealing with the water problems of their territory, have been accustomed to divide it into five climatic zones running transversely from west to east, the most northern being the Sahara, followed by the Sahel, the Sudan, the Guinea, and, lastly, the Forest zone in the coastal area.² Both soil and climate appear to rule out any possibility of improving water supplies on an effective scale in the Saharan zone, while in the Guinea and Forest zones the problem is mainly that of improving supplies for health reasons. In the Sahelien zone, however, which lies north of a line drawn roughly between the Casamance and the centre of Dahomey, water problems have an important bearing not only on agricultural production but on the distribution of the population.

The possibility of irrigation from the rivers in Senegal has for

¹ W. G. G. Cooper, *Report on Investigation into the Water Supplies of the Northern Territories of the Gold Coast*, 1937, p. 21.

² *Le gouvernement général de l'Afrique Occidentale Française, Exposition coloniale internationale*, 1931.

some years been the subject of a special study centring on storage projects on the Baoulé and Bakoy, and these will be followed by an investigation of possible sources on the Bafing and Falémé.¹ At this moment, however, the chief interest is concentrated on the important irrigation enterprise undertaken in the French Sudan with a view to the development of the Niger basin. The project is largely due to the initiative of M. Béline,² who began his investigation of the area about 1920. The hydrography of the central section of the Niger presents features of singular interest. In the course of its great northward bend the river floods an enormous delta of its own building, the area of inundation being estimated at nearly 40,000 square miles. A series of vast but shallow depressions, including Lake Debo, are filled during the flood season and gradually dry up as the river falls again. These conditions continue to the neighbourhood of Timbuktu, where the river resumes a normal régime, but so great is the effect on the Niger of this dispersal of its waters, that high water does not arrive in British Nigeria till twelve months after the fall of the rains on the head waters of the river in French Guinea. The scheme for developing the Niger lacustrine area was originally inspired by the hope of supplying the French markets with cotton, but it also found some support as a link in the project for the Trans-Saharan railway. The prospects of the railway scheme, however, must stand or fall on its military value; the Niger river already provides a ready means of transport for the products of the Niger basin to the sea coast. The lack of an adequate resident population and ignorance of soil conditions indicated the need for some caution in approaching any major scheme of irrigation, and the French Government began its study of the problem in 1922 by utilizing the cotton research station of Niéncbalé, 110 miles below Bamako, as an experiment in colonization; it has now a well-established population of about 1,500.

A more extended experiment of this kind was made in 1931 on the Sotuba canal near Bamako, which had originated in 1925 as a combined project for the provision of hydro-electric power and a navigation channel to avoid the rapids on the Niger. The

¹ J. Brévié, *Discours à l'ouverture de la Session du Conseil de Gouvernement*, 1933, p. 98.

² See *Rapport sur le fonctionnement de L'Office du Niger*, 1935.

total cost was 20,000,000 francs, of which one-half represents the cost of the canal, which commands an area of about 21,250 acres. After a period of initial difficulties the scheme has begun to attract colonists, and there is now a population of 5,500 persons, mostly of local origin.

The major Niger irrigation project, which has its headworks near Sansanding, was approved in 1931. The barrage, of a total length of 5,981 feet, including a mobile barrage of 2,640 feet, will be completed in 1941, but the two main channels, the Macina and Sahel canals, will be ready at an earlier date and have already been utilized in 1935 and 1936 for irrigation by flood water. The project has involved the construction of an embankment of nearly forty-four miles in length extending as far as Macina, in order to protect from flood action the lands lying below the left bank of the Niger. Irrigation will be developed in stages, the first being estimated to command some 597,241 acres; the total area estimated as under command is 2,372,166 acres, but this includes, in addition to the irrigated lands, a considerable area benefited by seepage. The cost of the main engineering work up to the first stage is estimated at 300,000,000 francs or (at the rate prevailing before devaluation) £3,750,000; the secondary works will probably require the expenditure of an equivalent sum. Since 1932 work on the development of the Niger basin as a whole, including mining surveys and the general improvement of agriculture over a wide area, has been entrusted to a special state organization, the *Office du Niger*, with M. Béline as Director-General, and the development expenditure on the Sansanding scheme forms part of this general account; some share of the development will fall also on the revenues of the colony, which has already assumed responsibility for the protective embankment and some of the experimental farms.¹

It is not possible at this stage to forecast the financial returns of the Niger schemes. Experience at Sotuba and that gained in the somewhat similar conditions of the Gezira project in the Anglo-Egyptian Sudan have shown that native colonization, if conducted by gradual stages, need not present the difficulty which

¹ For the Niger Scheme, see *Premier congrès soudanais de technique et colonisation africaines*, 1936, vol. ii, pp. 114; S. H. Frankel, *Capital Investment in Africa*, 1938, Chap. V, sec. ii.

was once anticipated on account of the local shortage of population. The experience of the Diré Company, which has had since 1919 an agricultural station at Goundam, leads to the same conclusion; there is at Goundam a native colony of 320 families, which it is hoped to increase shortly to 700. Only part of the area commanded by the Sansanding scheme is suitable for cotton and about half the area will be devoted to rice, of which Senegal imports in certain years nearly 80,000 tons from Indo-China. Every credit must be given to the *Office du Niger* for the careful preliminary investigation which it has made of all soil and agricultural conditions, but there remain factors which can only be tested by further experience. It is a characteristic of African soils that they are easily exhausted and require regeneration by long fallowing or artificial fertilization. It is noteworthy that the Gezira scheme, with its full command of Nile water, began with a three-year rotation of cotton and has had to fall back on a four-year rotation. The *Office du Niger* has conducted experiments with apparent success in both green-manuring and artificial fertilization, but it still remains to be seen how far the Niger basin soils will react over a period of time to continual cropping, especially in the hands of a population hitherto inexperienced in agriculture. The loan funds from which the work is being constructed carry a high rate of interest ($5\frac{1}{2}$ per cent.) and delay in development will lead to a proportionate accumulation of interest charges.¹ The work is so important that it is to be hoped that the Government of French West Africa will give to other administrations the benefit of a full statement of the progress made, accompanied by a capital and revenue account and figures of 'duty' and cropped area, compiled on a basis which will allow comparison with similar works elsewhere.

Elsewhere in the Sahelian and Sudanese climatic zones of French West Africa the main problem, like that of Northern Nigeria, is that of stabilizing and extending agriculture by drawing on underground water supplies for the provision of drinking water. The French authorities, acting through the local *sociétés de prévoyance*,² have of late years largely increased the cultivation of groundnuts by constructing open wells for drinking-water, and have thus been

¹ See Chap. XX, p. 1451.

² See Chap. XXI, pp. 1477-80.

able to effect a redistribution of the population in part of Senegal in order to relieve soils which have shown exhaustion from the continuous cropping of ground nut. The *sociétés de prévoyance* have been utilized for the same purpose in the French Cameroons. In the northern areas of French Equatorial Africa preliminary studies have been made into the possibility of using the Logone and Chari rivers for irrigation, but with this exception no measures calling for notice have been taken to deal with the problem of water supply. The territory has a large river system in the Ubangi, Congo, and Gabon Provinces, but the rainfall conditions in these areas have been held to make it unnecessary to consider the construction of irrigation works.

III. FUTURE LINES OF DEVELOPMENT

The facts to which the preceding paragraphs have made reference seem to show that in the present conditions of Africa, large-scale irrigation undertakings are likely to prove of less value to general development than smaller works auxiliary to agriculture or stock-raising, or the provision of drinking-water supplies from underground sources or the storage of rainfall. There are many areas in which inadequate attention would seem to have been paid hitherto to the need of the latter provision. The use of loan capital for the development of smaller works, such as a borehole, well, or small rainfall storage dam, is restricted since, unlike the larger irrigation work, they cannot give a direct return to capital outlay, and in many areas a considerable percentage of drilling failures is to be expected. It is, however, indirectly productive, and some part at least of the interest charges would be met by the resulting increase in general taxable capacity. In French West Africa it has been found that the *sociétés de prévoyance* are able to meet from the extension of cultivation rendered possible by well-sinking the service of loans advanced by the *Crédit Agricole*. It is, at all events, clear that the extension of drinking-water supplies in semi-arid tracts has claims on the available resources of the African territories which are certainly not less than those of medicine or education as a measure conducing to the promotion of native welfare.

IV. THE DEVELOPMENT OF MAJOR IRRIGATION WORKS BY PRIVATE CAPITAL

The difficulty arising from the engagement of state finance in major irrigation undertakings has given occasion to the question whether they cannot be suitably developed by the aid of private capital. Their management, however, involves matters so vital to those who become dependent on them that the governments in Africa may well share the objection which has been felt in India against entrusting them entirely to private control, and this is likely to be all the stronger when cultivation is in the hands of Africans. In a situation in which the land is of little use without the water, the control over water differs little from proprietorship over the land. For this reason many have preferred to advocate systems in which development is shared between the state and private capital.¹ The small settlement at Diré mentioned above, though nominally of this class, is hardly in point, since the state has no effective share in the enterprise, but the Gezira scheme in the Anglo-Egyptian Sudan provides an illustration of development which has been described as a tripartite partnership of the state, private capital, and the cultivator, the study of which may be of value to other administrations. Construction began in 1913 in circumstances which resulted in a far higher capital charge than would have occurred under normal conditions: though no regular capital and revenue accounts have been published the cost of the canal and connected works may be taken at nearly £14,000,000. The commanded area was in 1937 estimated to be a little over 800,000 acres, which on the four-year system of rotation now in force gives an area under cotton, the only productive crop, of about 200,000 acres. Possession of the necessary land was obtained under a land ordinance by which the state took over all rights on long lease subject to a fixed annual payment to right-holders. The capital cost of the work, except that of subsidiary canalization, was borne by the state, which also bears the annual outlay on the maintenance of irrigation. The granting of tenancies to cultivators and the management of the cultivation have been entrusted to the Sudan Plantations Syndicate, which maintains a

¹ See H. M. Leake; *Studies in Tropical Land-Tenure*, 1933.

large European technical and supervisory staff. It markets the cotton crop and the proceeds, after deducting its charge for ginning and marketing expenses, are now divided in the proportion of 20 per cent. to the Syndicate, 40 per cent. to the government, and 40 per cent. to the cultivators. The mechanical ploughing for the cotton crop is carried out by the Syndicate, which also supplies seed, but these charges are recovered from the cultivator, who provides at his own cost all other labour involved such as weeding, picking, and clearing watercourses. The conditions of tenancy lay down that he must devote a prescribed part of each holding to subsistence crops, but no recovery is made if canal water should be used on their cultivation. The system gives a high measure of efficiency in cultivation, yielding a high-grade and uniform product which commands a specially good price in the cotton market; it is doubtful if the Sudan administration could have attained the same results without the aid of the Syndicate, which had previous experience of cotton-growing on the pumping stations in the Sudan, and whose large staff has shown itself as capable in the administration of the tenancies as in the technical aspects of cultivation. The cost of management—namely, the 20 per cent. of proceeds retained by the Syndicate—though undoubtedly high, represents the sum paid for an organization which has been of great value in the development of the Gezira; but it is a matter for consideration whether this could not now be reduced by a larger employment of a native trained agency. From the cultivator's point of view it may be said that the conditions have been adequate to attract and retain a sufficient number of tenants; it may be noted that in 1935 about 75 per cent. were local inhabitants or their nominees, 6 per cent. were from the western Sudan, 2 per cent. from Nigeria, 9 per cent. from French Equatorial Africa, and 3 per cent. from other sources. They are adequately secured in the growth of subsistence crops, and in a year of average cotton prices each holder would appear to receive an average yearly sum of £20 to £40 in cash from his share of the cotton, but from this he has to pay the cost of any labour which his family cannot supply. In the years of reduced cotton prices following the general depression the cash returns were reduced to a figure which left the tenants with a considerable debt to the Syndicate on account

of ploughing and seed and subsistence advances, and these had to be written off by it with the assistance of government. The tenants are materially better off than their neighbours, who still depend largely on grazing and the cultivation of inferior subsistence crops, but their position as tenants under a close supervision does not give them the same sense of stability, or the same interest in their holdings, as is secured by the conditions of tenure in the somewhat similar undertakings in India. It is only fair to add, however, that tenants on the Gezira have come to the settlement with a very different background and with a lower capacity as colonists than the Indian cultivator, while, as shown above, many of them come from other territories and would not in any case be permanent settlers.

CHAPTER XVI

SOIL EROSION¹

I. TYPES AND EFFECTS OF EROSION

It is only in the last few years that soil erosion has become recognized as one of the major problems facing the governments and peoples of most African territories, and as a problem which is growing yearly more acute. This is not to say that erosion is in itself a new factor. On the contrary, it has been going on since the world began; it is the process by which soils are formed from the parent rock, and by which the topography of the earth is moulded. The problem which Africa has to face arises from the acceleration of the normal rate of erosion by reason of the activities of man. It is in this sense of accelerated erosion that the term 'soil erosion' will be used in this chapter.

Erosion, in this sense, may be defined as mechanical changes in the soil, brought about by the agencies of wind and water. These changes follow upon and themselves accelerate the destruction of the vegetal covering normally protecting the earth's surface, and this destruction of vegetation, be it forest or grass, is the essential cause of accelerated erosion. The natural tendency of the earth is to cover itself with a protective shield of vegetation, whose composition is determined by conditions of soil, rainfall, and climate. For every part of the earth's surface there is a final stage of equilibrium between the vegetation and its environment, known to ecologists as the climax, which will be reached by the vegetation, provided that it is left free to develop. The intervention of man frequently upsets this delicate balance, and reverses the order of plant succession. African rain-forests, for instance—a climax type of vegetation—rarely recover from cutting or burning, but are usually replaced by park-like forest of a lower ecological type, sometimes called savannah. This savannah forest, in turn, may be reduced by frequent burning to a sparsely bush-clothed veld. Finally, overstocking and the continual grazing and trampling by cattle may so weaken the grasses that they succumb to drought, and the veld is then transformed into desert practically devoid of vegetal cover.

¹ This chapter was largely drafted by Mrs. Elspeth Huxley.

It is at this stage that erosion through the agencies of wind and water becomes acute. Vegetation normally protects the soil from the impact of falling rain, facilitates the percolation of rain water into the subsoil levels, takes up surplus moisture in its foliage, reduces the rate of evaporation, and shields the surface of the soil from wind. Its removal bares the earth to the direct impact of rain and wind, and to the drying action of the sun. These three elements may then in a very short space of time strip the mature topsoil wholesale from the earth's surface and remove it as silt in rivers or as wind-borne dust. This leaves exposed the sterile subsoil, sand or rock, incapable of supporting those types of plant life which can be utilized by man or his animals. In extreme cases the process may go so far that it becomes, like certain chemical reactions, irreversible: that is to say, nothing that man can do will restore the fertility of the land. This destruction of soil fertility, the most spectacular result of erosion, is the end product. The earlier stages are far more widespread and constitute the more serious problem; for in these earlier stages erosion can still be checked.

There are, broadly speaking, three types of erosion: sheet, gully, and wind. The first is the most widespread and dangerous, for it can proceed to a considerable length before any change becomes apparent to the eye. The primary cause is the cultivation of land on slopes without the use of terraces or other preventive measures. This form of erosion occurs to a greater or lesser extent on all slopes when the soil is left exposed and heavy storms are experienced; the tendency to it is increased where shallow ploughing has resulted in a hard pan a little below the surface; its severity varies with the type of soil and with the steepness of the slope. The first effect, which usually goes unnoticed, is the removal of the finer soil particles in suspension, leaving the coarser particles behind. These finer elements in the physical structure of the soil fill an important function in helping to bind soil particles into crumbs, upon whose size the quality of the tilth and the capacity of the soil to retain moisture and soluble plant food largely depend. Their removal leads to a deterioration in the capacity of the earth to support plant life. The coarser residual soil, moreover, leaches readily, and stores of humus rapidly become exhausted.

In more extreme cases the topsoil may be stripped bodily from the slopes and carried into the rivers by heavy storms. It is computed that many areas in the highlands of Nyasaland are losing soil at the rate of a quarter of an inch a year.¹ In Kenya an instance of the loss of 12 inches of topsoil in a year has been noted, and in one case an inch of soil was removed from a maize field in a single storm.² While sheet erosion is generally associated with cultivated land on hill-sides, it may also affect badly denuded grazing land in undulating plains; for example in Karamoja, in the Eastern Province of Uganda, observers have commented upon 'a vast sheet of muddy water rapidly moving over the surface of the country'.³

Gully erosion is more obvious, and frequently follows sheet erosion. When no vegetation is present to impede the flow of storm water, that proportion of rainfall not absorbed by the soil finds its way downhill in a series of rivulets whose channels are widened and deepened by every downpour. A vicious circle is set up. As the channel grows wider and deeper, the quantity and velocity of the water which pours down it after each storm grows also; and the power of the torrent to tear soil from the sides and bed of the gully is correspondingly increased. Gullies not infrequently start as small creases in the surface of a ploughed field and develop within a few years into chasms 20 or 30 feet deep. In the United States it is estimated that 13,143,000 acres have been destroyed by gully-ing.⁴ Almost any channel or track is liable to develop into a gully; in Africa roads, railways, and paths made by stock going to water or to their kraals are particularly dangerous. In South Africa and Basutoland this form of erosion has become particularly severe. Loss of soil is increased by the cutting back not only of the main channels but of tributary gullies, known in South Africa as sluits, which then spread outwards from the heads of the gullies as small lateral channels.

Both sheet and gully erosion are brought about by the action of water. A third form is that resulting from the action of wind.

⁴ *Report on National Planning*, National Resources Board, 1934, p. 171.

Open treeless plains, where no obstructions break the force of the wind, are particularly susceptible. In their natural state such plains are generally protected by grass cover, but when this grass is removed, either by cultivation or by over-grazing, wind erosion may strip the topsoil from the land. The most striking recent examples of this have occurred in the United States, where dust storms have robbed millions of acres of the great plains of their topsoil. In Africa dust storms have not yet developed on a large scale, but wind erosion is a factor of growing importance. The harmattan of West Africa carries with it sand particles from the Sahara and may be a factor in the spread of desert conditions in Northern Nigeria.¹ In north-western Kenya the recession of the waters of Lake Rudolph has left stretches of fine sand now being deposited over the land by the strong south-easterly wind which blows for a large part of the year.² So-called dust-devils, harmless enough when vegetation protects the earth, occur frequently in many parts of Africa, and, as cultivation extends, their significance as removers of topsoil cannot fail to increase.

The harmful effects of these three forms of soil erosion do not cease with the removal of the topsoil on which plants depend for their biochemical nourishment and physical support, and with a consequent decline in crop yields and in the carrying capacity of pastures. Erosion has several secondary results, of which the most important are: the silting up of dams and reservoirs; the escape of a large proportion of the rainfall as surface run-off before it can be utilized by plants; and a consequent fall in the level of the ground water-table, leading in turn to seasonal flooding and to the drying up of rivers.

Most of the topsoil that is moved downhill by sheet and gully erosion sooner or later reaches a river and is ultimately washed out to sea or into one of the great inland lakes. The Yellow River in China is said to transport 2,500,000,000 tons of soil every year.³ South Africa is said to lose some 187,000,000 tons of silt annually to the ocean.⁴ Rivers which have overflowed their banks regularly

¹ See below, p. 1103.

³ See G. V. Jacks and R. O. Whyte, *op. cit.*, p. 58.

⁴ *Final Report of the Drought Investigation Commission*, U.G. 49, 1923, p. 66.

for centuries, as, for instance, the Nile, or many of the great rivers of India, have deposited much of their load on the land, and built up rich alluvial soils; where, however, the load of silt is greatly increased by cultivation of hill-sides in the watershed, and where rivers are confined in their course owing to the depth of their valleys, the silt is carried out to sea. If, in its downward journey, it encounters reservoirs and dams, some of it is deposited, and the structure which was built to hold water rapidly fills with earth. This silting up of reservoirs has become a serious problem in the United States¹ and Australia,² and the same problem has already arisen in Africa. The loss of capital which follows the silting up of reservoirs is, of course, enormous; and more serious still is the consideration that, where reservoirs are built to store water for irrigation,³ the future of the whole irrigation project may be endangered. In India it has long been recognized that the chief argument for the reservation of the forests in the Himalayas is the necessity for the conservation of the sources of the great Punjab rivers and of the Ganges.

Soil erosion reduces the proportion of the rain water which penetrates into the soil and becomes available either for the support of plant life or for the replenishment of springs and wells; it increases the proportion which escapes into the rivers as 'surface run-off'. In Africa, where rainfall is so often the limiting factor in agriculture or stock-raising, this aspect deserves special consideration. Effective rainfall is that part of the total precipitation which is absorbed by the soil; that which escapes either by evaporation or as run-off is wasted. The rate of evaporation is everywhere high in Africa, and if losses by surface run-off are added to losses by evaporation,⁴ it will be seen that figures of total rainfall there are apt to be very misleading. As will subsequently be shown, the South African Drought Investigation Commission of 1923 did not believe that the annual rainfall was decreasing, but held that its effectiveness had decreased, since a larger proportion was being lost to the soil through increased surface run-off.⁵

Surface run-off increases where vegetal cover is reduced, since

¹ H. M. Eakin, *Soil Conservation Service Report*, 1935.

² Statement by State Rivers and Water Supply Commission in *Melbourne Age*, Sept. 22, 1937.

⁴ See Chap. I, p. 14.

³ See below, p. 1081.

⁵ See below, p. 1080.

obstacles no longer impede the flow of water, and the soil is no longer kept open and porous by the roots of trees and plants. By far the most efficient type of vegetal cover is deep-rooted natural forest, where run-off is often negligible. Grass, while less efficient than forest, is still much less wasteful than the majority of annual crops, for the run-off may be considerable when the land is left bare and trampled after harvest. Unless preventive measures are taken, a higher rate of surface run-off normally accompanies an increase in cultivation, and there can be no doubt that in Africa a bigger proportion of the rainfall is reaching the sea unutilized than was the case a century ago. To this extent, therefore, the severity of the droughts from which Africa so often suffers has been increased by man.

Springs and wells are fed by reserves of water stored in the sub-soil or rock underground. If these reserves dwindle, then wells dry up, springs are reduced to a trickle, and rivers that once flowed strongly all the year round fail altogether during dry periods and run only during and immediately after periods of rain. The more water lost as run-off, the less is available for underground storage: one of the most serious effects of increased surface run-off, therefore, is a fall in the level of the ground water-table. Such falls have been observed, and to some extent measured, in many parts of the United States;¹ in Africa the same phenomena of falling water-tables and dwindling rivers exist, although accurate measurements appear to be lacking. Examples of rivers which flowed all the year round twenty or thirty, or even ten years ago, and now consist of a chain of waterholes in dry weather and a muddy torrent in wet, have been quoted from almost all African territories. Apart from the Saharan examples,² the cause of which is a subject of some contention, there are many others. Dr. Robert Laws has listed twenty large streams that have ceased to flow in the Mombera District of Nyasaland since he first took up his residence there, nearly fifty years ago. The level of lakes in Uganda is steadily falling, especially Lakes George, Edward, and Kioga,³

¹ W. R. Chapline, 'Range Research in the United States', *Herbage Reviews*, vol. v, no. 1, 1937, pp. 1-13.

² E. P. Stebbing, 'The Threat of the Sahara', Extra Supplement, *Journal of the Royal African Society*, May 25, 1937, p. 7.

and in Kenya many once perennial streams have now become seasonal.¹

A corollary to the dwindling of rivers and streams during dry seasons is the increase of flooding in wet seasons. Storm waters, no longer checked by forest and bush, flow down gullies and hill-sides into the river-beds; and streams, suddenly swollen, become converted from feeble trickles into rushing torrents heavily charged with silt. It is now an accepted thesis that such flooding is greatly augmented and in some cases caused by deforestation of the watershed. In France, for example, the correlation between floods and deforestation has been demonstrated in the Savoy region. Between 1738 and 1912, 21 per cent. of the forests of this region were destroyed; and whereas during the eighteenth century only eight floods occurred in the area affected, in the nineteenth century the number of floods rose to thirty-eight.² It is at the time of such flooding that irreparable damage is done by the removal of soil in the form of silt. Evidence from many parts of Africa points to the fact that within the last twenty or thirty years such sudden floods, which often subside as quickly as they arise, have become more numerous and more extreme.

The question of a falling water-table needs special consideration in view of the fact that in many parts of Africa action is being taken, by the sinking of new boreholes, and the deepening of existing wells, to extend the water supplies available to man and beast; and indeed it has been suggested that a part of the solution of the overstocking problem lies in opening up new areas for grazing by the provision of wells.³ It is obvious that if the demands made on the underground water-store increase while available supplies continue to shrink and recede, wells provided by governments at considerable cost, with the idea that they will constitute permanent sources of supply, will afford only temporary relief, and will indeed create an even worse position. Catchment tanks and dams might be preferable to wells, as being cheaper and easier to construct and maintain.

Soil erosion leads to chemical changes in the soil too complex to

¹ H. L. Sikcs, *The Underground Water Resources of Kenya Colony*, 1934, p. 10.

be dealt with here, but all tending in one direction: to reduce fertility of the soil and so to impair its efficiency as a supporter of plant life. This, in turn, can have only one result, the reduction of the capacity of the land to maintain human or animal life. This point needs special consideration in Africa, where other factors may be causing, in many areas, a rapid increase in both human and animal populations; in parts of the continent the demands of population are already throwing such a strain on the land that its productivity is actually declining. It has been noted, for example, that in Northern Nigeria, on the fringe of the Sahara, 'the whole population is actually increasing whilst the means of supporting it are obviously and visibly decreasing'.¹ The highlands of Nyasaland are stated 'now to be incapable of supporting one half of the population that they did one hundred years ago'.² The same story can be told of many other parts of Africa, from the Sahara to the Cape; and in all cases the stripping of vegetal cover from the land, either by cultivation or by grazing stock, is one of the causes.

II. CONTROL OF EROSION

Excessive soil erosion can, fortunately, be remedied. Since the destruction of vegetal cover is the prime cause, the restoration of such cover is the most obvious remedy. Reafforestation is now regarded as essential for the protection of soil and of head-waters on steep slopes, especially in watershed areas. Actual replanting is expensive, and few administrations can afford it; but results of great value can be obtained by a closure sufficient to allow of a process of natural growth, even if it be of a 'secondary' nature. Protection of existing forests, now practised to some extent in all African territories, is a recognition of the essential part which forests play in the stabilizing of soil fertility, water supplies, and climate. The proportion of Africa's land surface under forests is, however, dangerously low, being less than one-third of the extent considered by experts to be the ideal, which is usually taken to be 30 per cent. though some officers would accept 25 per cent.³ On level or undulating land where protection from forests is not essential, it

¹ E. P. Stebbing, 'The Encroaching Sahara: the Threat to the West African Colonies', *Geographical Journal*, vol. lxxxv, no. 6, 1935, p. 609.

² A. J. W. Hornby, *op. cit.*, p. 8.

³ See Chap. XIV, p. 1000.

may still be necessary to provide a cover of grass if the soil is to be retained. But to restore the natural vegetal cover to all parts of the earth's surface threatened by erosion would mean the withdrawal from cultivation of large areas of agricultural land. This is obviously an impracticable course. The problem of the soil conservationist is therefore to devise means whereby agriculture and stock-raising can be carried on in regions susceptible to erosion without causing permanent damage to the soil. It is proposed here to review briefly those methods which have been devised and found to work satisfactorily.

(a) *On Cultivated Land*

The most ancient, universal, and effective method of increasing absorption and reducing run-off on cultivated land is the use of terraces. The origin of the terrace is lost in antiquity, but its use in Japan, China, the East Indian Archipelago, and the Mediterranean countries has enabled agriculture to be carried on, and large populations to be supported, in regions where erosion would undoubtedly have reduced the rich hill-sides to infertile rocky slopes within a few generations had no such measures been taken. Terracing is most highly developed in countries where rice is the staple crop.¹ In Africa, although rice is indigenous,² terracing (except where recently introduced by Europeans) is almost unknown, though the Chaga on Mount Kilimanjaro make use of it, and on Ukerewe Island, in Lake Victoria, an elementary form is practised. In recent years there have been developed methods by which the principle of terracing can be fitted into modern systems of farming at a very much lower cost than that of the traditional narrow-base structures, known as bench terraces, whose demands on labour are extremely exacting. The simplest of these methods is the construction of small earthworks, in the form of ridges or banks, which follow the contour of the slope and arrest the flow of water and the drift of soil. A somewhat more elaborate structure is the broad-base terrace, of which the Mangum terrace now widely used in America is a form. This requires the use of simple levels in addition to various specially adapted farm imple-

¹ J. Thorp, 'Soil Erosion in China', *Journal of Association of Chinese and American Engineers*, vol. xvii, no. 4, 1936, p. 183.

² See Chap. XIII, pp. 894-5.

ments for its construction; but, once built, it is a permanent and efficient structure. Cultivated land which is contour banked or broad-base terraced must thereafter be ploughed along the contour, which is in itself a minor preventive measure against erosion.

Apart from these and other variations of terracing, several simple anti-erosion measures have been devised. One such measure is the planting of narrow strips of a soil-binding crop (e.g. lucerne, clover, beans, Sudan grass, &c.) at intervals along the contour of the slope, the main crop being grown in between such bands of wash-resistant vegetation. This is known as strip-cropping. Another is the use of cover crops sown, as a rule, shortly before harvest in order to ensure that the land shall not be left without some protective vegetation after the main crop is removed. Other methods of avoiding erosion involve alterations in the basic system of farming designed to increase the humus content of the soil, and to reduce the period during which the land is left bare of vegetal cover.

It is now a commonplace of agricultural practice that the restoration to the soil, in the form of artificial fertilizers, of those elements taken from it by plants, is not enough to maintain fertility, however carefully the chemical loss may be made good. Without the addition of humus derived from organic matter, the land 'loses heart', the tilth deteriorates, and the soil's capacity to absorb and to retain moisture becomes seriously impaired. In this condition it falls an easy prey to erosion. An important factor in conservation, therefore, is to maintain the humus content of the soil. It is probably true to say that if there is one panacea which conservationists would like to see more generally applied than any other, it is the spread of mixed farming. This system ensures that a fair proportion of any given farm shall be kept under grass cover, and provides the means, in the form of manure, for maintaining the humus content and the physical condition of that part of the farm which is cultivated. If a grass ley is rotated with crops, moreover, the system ensures that every part of the farm in turn shall be rested, and its humus content restored.

Attempts are being made to introduce mixed farming in parts of Africa.¹ Where mixed farming is impracticable—as, for instance,

¹ See Chap. XIII, pp. 960-3.

in parts subject to severe animal diseases—humus content may be maintained by the addition to the soil of green manures or of compost. Green manuring with leguminous crops only proves effective in regions where rainfall is fairly well distributed; in regions of low and rigidly seasonal rainfall the ploughed-in crop does not break down satisfactorily. In these areas the break-down of organic matter—in this case crop residues, weeds, and waste material of all sorts—can best be effected not in the soil but outside it, in compost pits or heaps; the resulting humus, in a fine state of division and ready for use by the plant, is then applied to the soil. Adaptations of the method of humus manufacture in compost pits devised by Sir Albert Howard at Indore,¹ by which plant and other residues which would otherwise be wasted are put to good use in helping to maintain soil fertility, are being examined in several parts of Africa. In Kenya, for example, a District Officer has evolved a simplified system for the native farmer,² and the Agricultural Department has conducted a campaign in favour of a compost pit for every village.

(b) *On Pastoral Land*

Erosion on pastoral land is a result of the destruction of grasses by over-grazing, by trampling, and by veld fires. The remedy is to devise and apply a system of veld management which will adjust the numbers of live-stock to the capacity of the land to maintain them, and give the grasses a chance to re-seed themselves at suitable intervals. In working out such a system, the first step where possible is a survey to determine the carrying capacity of the land. This will vary greatly, not only in different years, but as between the dry and rainy seasons of each year. The next step may often be, therefore, to classify areas as dry- or wet-weather pastures, and to arrange for a rough system of rotational grazing between the two, which will give each area intervals of rest when the grasses can set and shed their seeds.³ Pastoral tribes, in their natural state, had worked out some such rough system for themselves, but often it broke down with changes brought about by

¹ A. Howard, and Y. D. Wad, *The Waste Products of Agriculture*, 1931.

² A. D. Hall, *The Improvement of Native Agriculture*, 1931.

³ See Chap. XIII, p. 971.

European rule; a well-known instance is that of the tribes in British Somaliland, where each tribe used at one time to have its own dry-season grazing ground, or *jilal*, which it guarded at the point of the spear.

The distribution of water has a vital bearing on the question of grazing control. Where rivers are few and far between and wells widely scattered, grazing is confined to belts on both sides of the rivers and to circles, centred on wells, whose radius cannot exceed the distance a beast is able to travel without water. In some regions, therefore, large areas of pasture in between these grazeable circles, and beyond the grazeable strips bordering the rivers, are useless for stock. In those regions the provision of new wells would release hitherto sterilized pastures for the use of stock.¹ Another factor which leads to the over-concentration of stock is the herding of cattle into kraals or *bomas* at night. The grass both within these enclosures, and on the tracks leading to them, is then totally destroyed, and the bare patches which result often act as foci of wind erosion. The substitution of a system of paddocking for that of kraaling is therefore one essential method of erosion control. Attention was first called to this question by the South African Drought Commission, which recommended a campaign to extend the use of fences, proof against jackals whose depredations are largely responsible for the custom which prevails in the Union of kraaling sheep.²

The control of fires is an essential part of veld management. Since time immemorial, pastoral natives have fired dry grazing in order to promote the growth of young green shoots; European graziers adopted the custom and often became its strongest supporters. Perpetual burning weakens or destroys the roots of grasses and plants, increases run-off, destroys organic matter in the soil, and hastens the progress of soil desiccation and erosion. It is particularly dangerous near the head-waters of streams, where devegetation leads to shrinkage of springs and to flooding after storms. The matter has been studied carefully in South Africa. The Drought Commission considered that 'the ultimate goal should be to stop all veld fires', but concluded that this was

¹ See Chap. XV, p. 1052.

² *Final Report*, op. cit., U.G. 49, 1923, p. 41, and see below, p. 1080.

impossible, and that steps should be taken to discourage them, and to encourage tree planting. Later studies¹ have suggested that total abolition may not always be desirable, since veld burning destroys ticks and in some areas (e.g. Natal) suppresses coarser grasses which mark the first stage in a plant progression towards scrub and towards forest.² This can only apply, however, to wetter regions, and to controlled burning. Experiments in the southern Cape Province suggest that if firing takes place before the grasses are dried out, the heat is less severe and destruction largely confined to the surface, not affecting roots or surface soil. The conclusion that uncontrolled veld burning is an unmixed evil is nowhere in dispute. The question of how to maintain control is, however, a difficult one, and a solution has not yet been found; there is, in the British colonies, an increasing tendency to utilize the rule-making powers of native authorities for this purpose, and if the measure is not always effective, it has at least an educative influence.

Other measures designed to strengthen the vegetal cover of the veld have been considered. One is the selection and breeding up of strains of grasses which will increase the carrying capacity of the veld. Considerable attention has been paid to this in South Africa, where Dr. Pole-Evans has selected and bred a large number of drought-resistant and heavy-yielding strains,³ and to a lesser extent in Kenya, where experiments in planting eroded areas with indigenous Kikuyu grass are being made. Allied to this method (whose chief disadvantage is its expense) is the introduction of exotic drought-resisting plants, such as Australian saltbush, to provide cover and food for stock. The planting of tree belts, the afforestation of hill-tops, the reconditioning of badly denuded areas by digging staggered trenches to arrest soil-wash on slopes, and the fencing and sealing of gullies by means of dams, are auxiliary methods of erosion control practised on pastoral land.

Finally, the complex question of the elimination of uneconomic stock cannot be divorced from that of veld management. If uneconomic stock is defined as animals maintained for purposes other than the supply of food and clothing or for sale, then a very large

¹ C. F. M. Swynnerton, *How Forestry may assist towards the Control of Tsetse Flies* (memo. presented at the 4th British Empire Forestry Conference), 1935.

³ See Chap. XIII, p. 972.

proportion of the cattle and goat population of Africa is uneconomic. The problem is a psychological one: so to change the attitude of the native towards his domestic animals that they become not tokens of wealth or a form of currency, but sources of income. This adjustment would admittedly involve a revolutionary change in a habit of great social and religious significance; but if it could be made, then natives might be taught to adopt such standard practices (at present often rejected) as the castration of inferior males, supplementary feeding, calf rearing, and, above all, the limitation of stock on any given pasture to a number which will not merely survive but will thrive on the available feed. Discussion on how best to persuade them to do so has been proceeding for many years. One main stumbling-block is that the bride-price is generally paid in cattle or goats among both pastoral and agricultural tribes. Efforts to encourage the payment of bride-price in cash have met with some response among educated Africans, but little among the bulk of the tribesmen. Various possibilities have been put forward, such as Sir Daniel Hall's suggestion of striking coins bearing the image of a goat or cow, or providing special tokens shaped like live-stock and redeemable in ordinary currency, to bridge the psychological gap between the use of animal and of mineral tokens of exchange.¹ No experiments, however, appear to have been conducted, and although the question is one of the most urgent of those arising from culture-contact,² anthropological studies have not yet indicated any method whereby substitution of cash for cattle and goats might be hastened.

Another method of approach is to encourage Africans to consume more meat, milk, and dairy produce, a procedure desirable not only on grounds of health, but because once a native has learnt to regard his stock as a source of food he is likely to attach importance to the quality of his cattle rather than to their quantity. Yet a third line of attack is to assist him to find an economic outlet for his stock,³ either by establishing meat factories which buy his cattle for cash, or by teaching him better methods of preparing his hides and skins, or by instructing him in ghee manufacture and the setting up of small dairies. The chief obstacle in the way of these methods

¹ *Report of the Kenya Agricultural Commission*, 1929, p. 31. See also Chap. XIII, p. 973.

² See Chap. II, p. 22.

³ See Chap. XIII, pp. 937-40.

(which are being applied in varying degrees to several territories) is the conservatism of certain pastoral tribes, and their lack of any strong desire to obtain cash. Cattle owners do not, as a rule, evince the same enthusiasm as other types of African for clothes and other trappings of civilization, and they have not the same need for furniture and household goods. Cash to them is often of less use than cattle. There are also external factors which govern progress on these lines; meat factories,¹ for example, can only absorb a limited number of cattle, depending on the demand for meat products; and the price offered for goats cannot be made attractive, since the only part which is saleable in world markets is the skin.

All these three lines of approach to the central problem of live-stock limitation—substitution of cash as bride-price, increased consumption, and increased sale—have been, and are being, followed. The difficulty is to make action effective before pasture denudation has gone too far to be reversed. In some quarters the opinion has been expressed that education alone will prove too slow a process. In some arid regions even three or four years of severe over-grazing, followed by soil denudation and perhaps wind erosion, may be sufficient to destroy a pasture. In Kenya, for instance, it has been suggested that parts of the Turkana, Suk, and possibly Wakamba and Mberere reserves have already been eroded by over-grazing to a point where pasture cannot be satisfactorily re-established.² It has therefore been suggested that government regulation of the numbers of stock allowed to graze over certain badly denuded pastures can no longer be avoided, and that compulsory culling of stock may have to be enforced if the land is to be saved. It is recognized that compulsory de-stocking would result in difficulties for the administration, and possible hardships for individual natives, but it is suggested that the alternative of permanently abandoning considerable areas of grazing land would in the long run involve greater difficulties and severer hardships. No pronouncement of general policy on this matter appears to have been made, and no compulsion has yet been applied in any purely native part of Africa³ to enforce

¹ See below, pp. 1093, 1098. South-West Africa has a factory at Okahandja.

² *Report of the Kenya Land Commission*, Cmd. 4556, 1934, pp. 241-6.

³ Compulsory de-stocking was introduced in the Ukamba reserve in 1938.

the reduction of existing flocks and herds; perhaps the only measure definitely aimed at this purpose is the special tax on surplus cattle imposed in Ruanda-Urundi. It may be said, however, that the adjustment of the numbers of stock to the capacity of the pasture to support them is the only ultimate method of controlling erosion on pastoral land. It is self-evident that an administration should, before taking any action, call in the aid of anthropological inquiry and advice.

III. EROSION AS A WORLD PROBLEM

Since the experience of other continents suffering from erosion is not without value to Africa, some reference to the problem in China, India, Ceylon, Japan, the United States, and Australia may be useful as a prelude to the further examination of the problem in Africa.

Erosion is believed to have played an important part in the decline of past civilizations. In Mesopotamia cities now buried in sand were once surrounded by thriving farms, and the degradation of rich and fertile land into desert—in some cases due, it has been suggested, to the silting up of irrigation works—is thought to have been a primary cause of the decay of a once thriving civilization. In ancient Greece the hill-tops, now bare, were thickly forested, and the hill-sides, now rocky and barren, were well protected with vegetation. Deforestation led to the stripping of topsoil from the hills and the consequent decline of Greek agriculture; quantities of silt were deposited along the lower reaches of the rivers, and marshes and swamps were created, with the result that malaria undermined the stamina of the people. The sterile rocky hills and bare deserts of Palestine, that hem in a small strip of cultivated coastal plain, were once relatively fertile and provided good grazing for cattle and sheep.

In the interesting bulletin lately published by the Imperial Bureau of Soil Science, describing the present position in regard to erosion in the most seriously affected countries, China and India are described as presenting the most conspicuous examples of 'man-made desolation'.¹ China has in its loess soil one of the most easily erodible soils in the world, and the mischief of erosion is all

¹ G. V. Jacks and R. O. Whyte, *op. cit.*, pp. 32 and 57.

the more noticeable because of the *laissez-faire* policy of past Chinese governments, and the impotence of the small landowner to check the damage single-handed. Erosion in India is most serious in the foothills of its mountain ranges, where gullies and floods devastate large areas; but over and above this, great losses are being incurred by misuse of grasslands. They are lands which can maintain themselves only under conditions of reasonable treatment; persistent over-grazing has so impoverished them that in many cases the village herds are driven to treat the bush growth as a reserve, with grave consequences in surface erosion. The measures taken by the Indian Government have by no means been as energetic as circumstances required. It maintains the great forest reserves, mostly in the hills, which are the chief protection for the flow of the rivers, and consequently for the Indian irrigation system; but some large forest areas have been allowed to go back into village hands with the worst results. In some areas efforts are being made to reduce overstocking by directing attention to the improvement in the quality of cattle; large cattle-farms have been started, and the castration of bulls has made considerable progress on a voluntary basis; but in other respects the devolution of authority to local governments, and by them to local self-governing bodies, has left the country without any effective means of meeting a problem which is essentially one that requires a co-ordinated attack. Perhaps the one measure which affords a useful precedent for Africa is the Act passed in 1902 to enable the *chôs* or gully erosion areas in the Hoshiarpur district of the Punjab to be closed periodically to grazing,¹ with a view to allow for the re-seeding of natural grasses.

Ceylon was one of the first of the British territories to recognize the significance of erosion, and in 1929 appointed a committee to investigate its problems.² It was 'appalled by the waste of soil', but beyond some permissive legislation regarding the preservation of hill-tops and the issue of regulations regarding the disposal of Crown lands, further action was deferred pending the result of a 5-7 year period of propaganda and education. On the other hand, Japan affords a case in which the mischief of erosion was not only

¹ *Report of the Punjab Erosion Committee, 1934.*

² *Report of the Committee on Soil Erosion, 1931.*

early recognized, but firmly countered by the administration. As far back as 1781 Japan engaged a Dutch engineer to apply a system of flood control by means of check dams in the valleys and revegetation on the hills. Thereafter Japan maintained a national policy of keeping the watersheds under forest in order to protect the valleys from floods. It is remarkable that although Japan is among the most closely settled countries in the world, no less than 67.2 per cent. of its area is under forest, compared with 8 per cent. in Africa. In 1897 a Forestry Act was passed making flood regulation compulsory; but where control measures based on check dams and revegetation are enforced on private land, the state contributes five-sixths of the cost. It is said that altogether ten times the value of eroding land has been spent in protecting it.¹

If some considerable attention is given to the case of the United States, it is because of the example afforded both of extensive research into the problems of erosion and of very comprehensive action taken by the state to remedy the mischief which inquiry has revealed. Before the coming of the white man, one-half of the country was estimated to be under forest, and one-third under buffalo-grass range. Colonization has led to the destruction of about half the forest, to the ploughing up of vast areas of grass-land, and to the introduction of cattle and sheep. The results have followed the courses outlined earlier in this chapter. One-third of the total area under crops is estimated to be suffering from advanced sheet erosion, and the security of another third is threatened. On grazing land the situation is no less serious. About 46 per cent. (884,000,000 acres) of the land area of the United States is under range, of which one-third (known as the public domain) is owned by the federal government; it is unfenced and no control was exercised over it by the federal government until three years ago. As a result, this land has been so severely over-grazed that some of it has been totally destroyed, and a large part, estimated at 122,500,000 acres, has been greatly depleted. The reason, as in Africa, is the increase of stock;² the present stocking of the range of six states is estimated to be 100 per cent. in excess of

¹ W. C. Lowdermilk, 'Erosion Control in Japan', *Oriental Engineer*, March 1927.

² *The Western Range*, U.S. 74th Congress, 2nd Session, Senate Document 199, 1936, p. 155.

their grazing capacity. The original grasses have been largely replaced by weeds which are not only greatly inferior as feed but do not form a true cover. The same fate has overtaken much of the range in private ownership, one-third of the total, and of the remaining third belonging to the various states. The desert has grown from 2.5 per cent. of the total land area to over 4 per cent.

The most spectacular examples of erosion are to be found in that part of the continent lying between the Mississippi and the Rockies, known as the Great Plains, which has been converted by the plough from the original buffalo range into the existing 'dust bowl'. Between 1880, when the covered wagon era ended, and 1930, some 189,000,000 acres of pasture were put to the plough. The greater part of the region has a rainfall of 20 inches a year or less, and it is now realized that the period of settlement coincided with a wet cycle. This fact, combined with the original fertility of virgin land and with high prices, at first enabled farmers to make a living by growing crops for which conditions were not suited, on units of land which were uneconomic. The combination of a dry cycle and low prices between 1930 and 1936 revealed the basic weakness of the system. Wind erosion removed the topsoil in dense dust storms from vast areas that should never have been ploughed. It is estimated that 8,738,000 acres of farm land have been destroyed, and a further 82,353,000 severely damaged, by wind erosion.¹ There are, it is estimated, some 75,000,000 acres of land which should be retired permanently from use, because it 'is so poorly adapted to farming, and has deteriorated so rapidly, that nothing is in store for the inhabitants but extreme poverty and wretchedness'.² Some 10,000,000 acres have been bought by the government, turned into national parks, and the inhabitants moved and resettled elsewhere. Since 1930 it is estimated that some 40,000 families, or 165,000 people, have left the Great Plains area and sought a living elsewhere.

Vigorous and costly measures are now being taken to deal with erosion on a nation-wide scale; the details are only important where they indicate action which may have a possible application to Africa. The Soil Erosion Service set up in 1933 has now been

¹ *Report on National Planning*, op. cit., pp. 168, 171.

² *The Future of the Great Plains*, 75th Congress, Document 144, Feb. 1937.

enlarged into the Soil Conservation Service, with an annual vote which at present stands at £7,000,000. The indiscriminate use of the public domain for grazing was controlled by the Taylor Grazing Act of 1934; the Resettlement Administration, set up in 1933 to buy up hopelessly eroded land and to resettle the inhabitants elsewhere, had, before its dissolution in 1937, spent some £90,000,000 on these objects. In addition to these direct government measures, the spread of conservation practices was further stimulated by the passage of the Soil Conservation Act early in 1936. Under this Act farmers are directly subsidized for withdrawing land from certain soil-depleting crops, notably maize and cotton, and putting it under soil-conserving crops or under pasture. The main object of the Act is to reduce the acreage under certain crops grown for sale; it is, however, having a considerable effect in combating soil erosion and exhaustion.

Up to the middle of 1937 the Soil Conservation Service had established 156 erosion control projects, varying in size from projects covering a few thousand acres to a project in the south-west covering 17,000,000 acres and embracing the whole Navajo Indian reservation. The essential features of all projects are the same. The farmer undertakes to plan his farm operations on lines laid down by the Soil Conservation Service, and the Service agrees to assist him with a specified amount of mechanical aid, extra labour, and materials, not only in anti-erosion works such as terracing and check dams, but also in alterations in the system of cultivation or treatment of grazing areas. Both in cultivated areas and on range land, the Soil Conservation Service has proceeded some way along the road towards control which Africa has yet to travel, and nearly all the methods followed in the United States have possible applications in Africa. An interesting illustration is afforded by the work of the regional division centred on Albuquerque, N.M., where the Service is operating in an arid tract with a rainfall of 10 or 15 inches, except in the higher parts. Water is very scarce. Through the region run the upper section of the Rio Grande river and several of its tributaries; it includes the Navajo Indian reservation, which is heavily overstocked with cattle, sheep, and ponies. Soil erosion is far advanced. The problem is a dual one: to protect the head-waters of the rivers so as to control floods and silting, and

to restore the depleted pastures. The first is being met by the establishment of two projects, one covering the head-waters of the Rio Grande, and the other the watershed of the Gila river, where flood-control works and reafforestation are being carried out. The second is being tackled by reduction of live-stock, by checking and reclaiming gullies, and by applying a carefully worked out system of pasture management. In the Navajo reservation a cut of 28 per cent. in live-stock numbers was claimed as having been completed by July 1937.¹ Considerable reluctance to cull their stock was displayed by the Navajos, but anthropologists were engaged to advise how the Indians might best be approached, and finally an agreement was signed with the Indian tribal council. As the result of a practical demonstration of the value of fencing and pasture control, as evidenced by the state of the live-stock, the opposition to stock reduction and pasture management appears to be weakening. At the same time the spread of gullies is arrested by throwing up low dikes or 'spreaders' around the heads, so that flood water is spread fanwise over the land and stimulates the growth of better grass. Officers of the Service who deal with the Navajos have, of course, one advantage over administrators who deal with African natives, in that the Navajos keep sheep primarily for profit, and do not have the same emotional objections as the Africans to the sale of their stock.

In Australia scientific opinion seems to hold that the settlement of certain regions was pushed too far and carried out too hastily. In Victoria, for instance, land policy in the eighties led to the cry: 'Settle men where the big trees grow.' The forests of the Otway region in the south-west of the state, which at that time had an 80-inch rainfall, were opened to settlement and then cut and burnt down. The cultivation that replaced them was subjected to heavy wash, and to-day most of this land has been abandoned. A committee has now been set up to devise means of combating wind erosion. Provisions for stopping cultivation or burning near water-courses, and for maintaining a certain percentage of each farm under vegetation, have been laid down.²

The watershed of the Murray river presents a special problem. The drainage area of the Murray comprises one-fifth of Australia, and in it live three-quarters of the population; it also supports a big irrigation system which plays a vital part in Australia's economy. Erosion in many parts of the watershed is causing concern; increased run-off is occurring in winter and spring, and the summer fall of the level of rivers and streams is greater. The trouble is blamed principally on the burning of pastures in the catchment area. Experience in Australia has been that burning eventually kills out the grass, impoverishes the land, and promotes the growth of useless scrub. Proposals have been made to dedicate vulnerable sections as forest reserve, to reafforest denuded areas, and to revise grazing leases so as to control over-grazing.

IV. THE SITUATION IN DIFFERENT TERRITORIES OF AFRICA

(a) *General*

Africa's climatic conditions are specially favourable to the development of erosion. Progressive deforestation has been going on for centuries, thanks to the practice of shifting cultivation,¹ and has resulted in the existence over wide areas of a degraded, open type of vegetation which does not shelter the soil so well as forest, and is more susceptible to drought. Forest destruction may have adversely affected the rainfall, although this is not established beyond doubt. All that is certainly known is that forest does both induce precipitation by cooling the atmosphere above it, and conserve soil moisture by reducing evaporation. The great loss of forest which Africa has sustained must, therefore, have led to less frequent precipitation and to an increased loss of soil moisture, due to the higher evaporation rate, in those regions where it has been destroyed.

The system of shifting cultivation, although wasteful, had the advantage that, after two or three years' use, every piece of land was rested, often for a considerable number of years.² This not only allowed the soil to accumulate organic matter but safeguarded it from severe erosion, since land that was resting reverted to bush

¹ See Chap. XIII, p. 879.

² See also G. V. Jacks and R. O. Whyte, *op. cit.*, p. 33 regarding *taungya* in Burma.

and grass. At any given time, therefore, the greater part of the land was under vegetation, and so relatively safe from erosive influences. The effect of European rule has been, in almost every territory, to exaggerate several of the factors which lead to soil erosion. In the first place it has led to increases in population in certain areas, with the result that more land is needed to grow food. The concentration of natives in reserves, especially in South Africa and Kenya, has been an important factor in increasing erosion. Commercial crops now occupy very large acreages and mean that more and more land is put under cultivation. Again, the first agricultural lesson learnt by Africans has often been to give up their old custom of growing all their crops together on one plot, and to grow a single crop of, say, beans or maize, in rows. Mixed cropping kept a permanent vegetal cover on the land, but crops planted in rows expose the soil to erosive influences. Finally, the introduction of the plough has not proved an unmixed blessing. By greatly extending the area which an individual can cultivate it has greatly extended the area exposed to erosion, since native peasants have seldom combined ploughing with protective measures such as terracing and strip-cropping. In several of the British dependencies (e.g. Nigeria and Nyasaland) the Agricultural Departments have adopted a 'go-slow' policy in regard to the introduction of ploughs, until conservation measures and 'mixed farming' in particular have been more widely applied.

The very considerable increase in land under cultivation has led inevitably to a shortening of the period of bush-fallow. Land which would previously have been left alone for twenty years is now recultivated in four or five, or even less. It has been estimated, for example, that in the most crowded parts of the Kikuyu reserve in Kenya, 1 acre in every 3 is now under crops, whereas thirty years ago only 1 acre in every 10 or 12 was cultivated. The result is a gradual depletion of the soil's organic and mineral resources, and the removal of vegetal cover from a larger area of land. Added to this is the fact that cultivation is being pushed on to the more unfavourable land which is often on steep slopes, and therefore particularly susceptible. The natural conclusion is that sheet erosion—always, as has been pointed out, invisible to the naked

eye in its fairly early stages—is beginning to take place on the cultivated soils of Africa on an accelerated scale.

Live-stock populations are, undoubtedly, increasing at a much more rapid rate than the human. This is due primarily to the control of animal diseases by veterinary science. The most notable example is that of rinderpest, which used periodically to sweep over the African plains with the rapidity and ferocity of a veld fire, decimating the cattle populations. Other diseases such as pleuropneumonia, anaplasmosis and, to a lesser extent, East Coast fever have also been brought under control. The great epidemic that began in 1889 had its influence on the political history both of Kenya and Southern Rhodesia. In some areas the number of live-stock has doubled, while nothing has been done simultaneously to increase the capacity of the pastures. Goats have been condemned on all sides for their destructive feeding habits. They are seldom killed for food, and are economically of low value. Although skins have a steady sale and are exported in large and increasing quantities from both East and West Africa, the price is low. Among many tribes the bride-price is still largely paid in goats. With increasing prosperity the number required for this purpose has doubled or trebled, with the result that far more goats have to be kept to achieve the same end.

So much for the general situation in Africa as a whole. In the following pages an outline will be given of the position in each territory, and of the measures being taken to deal with it.

(b) Union of South Africa

Accelerated erosion is no new problem in the Union. Warning voices have been raised for the past half-century; but until recently little or no attention has been paid to them. In 1904 a Farmers' Congress passed a resolution urging the government to inquire into the serious shrinkage of water supplies due to the formation of sluits and to rapid run-off. The Director of Irrigation drew up a memorandum on the subject, citing, as the main causes, deforestation, overstocking, veld-burning, and kraaling of stock, but nothing came of the discussion. A select committee of the Senate which considered erosion in 1914 received much evidence concerning the loss of vegetal cover and the shrinkage of rainfall

within living memory. It was stated, for example, that in 1879 the Orange Free State was covered with bush grass interspersed with reedy pools, whereas by the time of the inquiry the pools had dried up and the grass had suffered badly from over-grazing. In 1919 occurred the most serious drought the Union had experienced. One result was the appointment of the Drought Investigation Commission, which in 1923 issued the most outspoken report hitherto produced on the subject of desiccation, pasture management, and erosion in Africa.

The report dispelled the generally prevailing idea that South Africa's rainfall had decreased. No evidence, it stated, had been submitted to prove that any change had taken place in precipitation; but 'the rains of the last generation, falling on unbroken, under-stocked grazing lands, were more lasting in their beneficial results than rains of equal magnitude falling to-day on veld over-stocked, tramped-out, semi-waterproof, hard-baked by sun and veld fires'.¹ The severe losses of the 1919 drought, the Commission concluded, were caused mainly by faulty veld and stock management. Over-grazing and erosion were widespread and growing rapidly worse. The power of the surface of the land to hold up and absorb water had been diminished; pastures had deteriorated, perennials having given way to annuals and weeds; the water table had fallen; rivers had become more seasonal in flow, and their silt loads had increased. A number of remedies was proposed. One was the abandonment of the system of kraaling live-stock at night, due to jackal depredations, and the substitution of paddocking. The Commission estimated that if kraaling were abolished throughout the Union the resulting improvement in the sheep population would bring in an extra £13,000,000 a year to South Africa. The importance of the control of veld burning—with the ultimate aim of its abolition—was emphasized. The Commission also recommended, *inter alia*, the provision of reserve fodder for stock to tide over dry periods; the provision of more watering places for stock; grazing control to ensure periodic resting of pastures to allow for re-seeding; and an extensive scheme of reafforestation combined with protection of catchment areas.

Since the publication of this report, which was not followed by

¹ *Final Report*, op. cit., U.G. 49, 1923, p. 5.

any large-scale government action until ten years later, further evidence of the extent and effect of erosion has accumulated. No province has escaped damage. The carrying capacity of the Union's natural pastures is much lower than it was twenty years ago.¹ Studies of silting show that the loss in the storage capacities of four important reservoirs, all built between 1920 and 1925, due to the accumulation of silt,² was in one case 43 per cent. and in the three others 33 per cent., 25 per cent., and 14 per cent.

A point of significance is that silting of reservoirs increases the proportion of surface to total volume of water and aggravates losses from evaporation, which are in any case extremely high in Africa. As a corollary to the silting up of old rivers, the creation of new ones—due to the extreme development of gullying—has been observed. The Brak river (Britstown District), for example, which by 1907 was 300 feet wide and 15 feet deep, did not exist at all sixty years before.³

South Africa is predominantly a pastoral country, and less than 15 per cent. of its area is estimated to be suitable for any form of cultivation. Its primary problems in erosion control, therefore, are, first, to arrive at a system of veld and stock management which will maintain a permanent cover of useful grasses on the veld, and, second, to make the fullest use of its water supplies. Having regard to the fact that South Africa is a country of erratic rainfall with frequent dry seasons, the amount of live-stock now maintained is a major obstacle to the solution of these problems. The sheep population rose from 12,000,000 in 1904 to 45,000,000 in 1932, and the cattle population from 3,500,000 in 1904 to 10,500,000 in 1930. The Department of Agriculture is carrying out experiments on such matters as the effect of rotational grazing, artificial fertilizers, and other factors on veld management; the use of supplementary pastures; and the breeding and selection of drought-resisting strains of grass. Propaganda is conducted among European farmers to persuade them to paddock their land; to reduce veld burning; to plant trees; to ridge-furrow or terrace

their land; and to preserve flood water in small dams.¹ A beginning has been made in watershed control by the purchase of land on the Outeniqua mountains (Cape Province) and on the Swartberg mountains. Additional areas on the Drakensberg are being brought under control as the leases expire. On this government land, grazing and burning will be prohibited, and, as funds permit, reafforestation will be carried out.

Arable land, although it occupies a small percentage of South Africa, is of great economic importance, and here erosion is increasing in severity. 'A problem . . . which is assuming larger and larger proportions, is the question of abandoned lands which have become exhausted and are unsuitable for crop production. These abandoned lands, which already constitute a large proportion of our arable lands, especially in the maize belt, not only serve to aggravate the problem of soil erosion, but in addition the vegetation growing therein consists mainly of weeds and inferior grasses which are naturally wholly unsuitable for grazing.'² The Department is striving to bring these dangers home to the European arable farmers by propaganda, and to persuade them to control erosion by contour banking and by the planting of American aloes to reinforce the banks. Wind erosion is also said to be increasing 'at an alarming rate each year'.³ Methods advocated to check it include leaving strips of unploughed land at intervals across the field, the planting of saltbush or spineless cactus strips, and the provision of tree belts.

The creation of dongas and sluits, and the waste of rain water through run-off, are two important and allied erosion problems. They are being jointly tackled by a scheme launched by the government in August 1933. The object is to assist European farmers to build small dams. After about two years a total of 12,959 dams had been built, and an estimated total of £1,801,075 spent on anti-erosion works, mostly by the farmers themselves. During the year 1936-7 the number of dams applied for and approved was 18,060, the preliminary estimated cost being

£2,163,260, while the preliminary estimated cost of anti-erosion works was £385,581. A further government scheme has recently been put into force to encourage landowners in coastal areas to reclaim drift sand areas, which have lately been spreading at an alarming rate.

Soil erosion has reached an equally, if not more serious stage in the Transkei and in the native reserves. The Native Economic Commission of 1930-2 concluded that all the reserves were overstocked, and that parts of some of them were in danger of reversion to desert conditions.¹ In the Transkei about 1,500,000 sheep have to live on about 9,000 square miles of pasture. Grazing lands, as a result, are trodden out and re-seeding rarely occurs; forest and bush have virtually disappeared. Gullies have everywhere grown out of cattle tracks leading to water or to dips. Money for reclamation was first voted by the Transkeian Council in 1926, and a start was made with the check damming of gullies. In 1932 construction of store dams, a costly measure, was abandoned in favour of the diversion of storm waters from the heads of gullies and the planting of grass on the donga sides. Between 1926 and 1936 the Council spent £77,832 on erosion control, which included fencing of gullies and contour ridging of land.² In parts of the Transkei and Ciskei up to £3 and £3 10s. an acre is being spent on anti-erosion measures such as damming and fencing gullies and planting wattle. Over the native reserves as a whole, an annual sum of about £7,000 has been spent by the Union Government in recent years on small conservation works for irrigation purposes.

At the end of 1933 an attempt to tackle the problem in the native reserves was started by the Native Affairs Department, with the threefold object of combating soil erosion generally, of providing storm-water irrigation, and of contouring agricultural land.³ A few badly eroded areas were reclaimed by fencing and the prohibition of grazing. The Native Affairs Department policy is now based on the assumption that grazing control, veld management, and overstocking deserve prior consideration over reclamation works. It has been estimated that 75 per cent. of the total area of Zululand

¹ See Chap. XIII, p. 971.

² See Chap. IX, p. 531.

³ *Combating Soil Erosion in the Native Reserves of the Union*, Department of Native Affairs, 1934, p. 3. See also Chap. XII, p. 808.

is affected by erosion. Production is said to have been reduced by 10 per cent. by this factor; and if nothing were done to check the spread of erosion, production would fall by 40 per cent. in the next twenty years. The Native Affairs Department's programme aims at a drastic reduction in the number of scrub bulls, at the improvement of cattle by means of selection under the 'bull camp scheme', and at the introduction of a six-year rotational grazing practice. The application of this programme is still in the early stages. A compulsory fencing proclamation was issued in 1931, but has not yet been applied on any large scale. It has been used in the M'singa region of Zululand for fencing off gullies.

(c) *Basutoland*

The greater part of Basutoland is mountainous and is inhabited by cattle owners. The population has recently increased to a remarkable degree. In 1898 it was estimated at 256,000; by 1931 this estimate had grown to 570,000. The rainfall is badly distributed; a long dry season allows the soil to dry and crack, and then torrential storms occur. Given these premises, erosion would appear inevitable, and in fact there are probably few parts of Africa that can produce more marked examples. The problem is principally one of soil wash from the steep hill-sides, which are mainly cultivated, and of gullying, which in 1935 was estimated to have affected 10 per cent. of the total arable land.¹ Gullies, often up to 40 feet deep, cut across almost every valley bottom. On the higher elevations, mainly over 7,000 feet, over-grazing has killed the nutritious grasses, and led to the invasion of the inedible weed 'bitter karoo' and of a ragweed poisonous to horses.

In 1935 Sir Alan Pim described soil erosion as the most pressing of all its problems. As a result of his recommendations a Director of Agriculture was appointed, and placed in charge of anti-erosion operations. Work began early in 1935, and in August 1936 an interest-free loan of £160,233 was made from the Colonial Development Fund to finance the scheme.² The principal part of the work is to arrest the spread of gullies by fencing gully heads, diverting storm water by the extensive contour ridging and terracing of

¹ *Report of the Commission on the Financial and Economic Position of Basutoland*, Cmd. 4907, 1935, p. 135.

² See Chap. XV, p. 1038.

arable land, and planting grasses to re-establish croded pastures. Existing gullies are also being reclaimed by means of earthworks on which a cover of Kikuyu or native grass is established, and by planting trees. At first the local population was suspicious, and considerable opposition occurred, trees in some cases being rooted up. Two years of work and propaganda dispelled fears, and the people are now giving the project their full support, even though the making of contour ridges and broad-base terraces entails the upsetting of all existing boundaries of fields. The area to be reclaimed is estimated at 150,000 acres, and the cost at £1 an acre; it is hoped to complete the work in ten years. Erosion control in Basutoland has an importance transcending its own borders, since the watershed of two important rivers, the Orange and the Caledon, lies within the territory.

(d) *Swaziland*

Although in Swaziland overstocking is not so grave a problem as it is in Basutoland, it has of recent years become increasingly serious. Another danger to the soil comes from the extended use of the plough. Unless care is taken erosion will result from the up and down hill ploughing which is already a common practice.¹

(e) *Southern Rhodesia*

Only 0.5 per cent. of the area of Southern Rhodesia is cultivated, so that arable erosion is not quantitatively severe. On the other hand, it is clear that the smallness of the area under cultivation makes such land all the more valuable; and the fertility of a considerable part of it is threatened by erosion. The soils, derived mainly from granites and sandstones, appear to be relatively erodible, and in the older cultivated districts such as northern Mashonaland many areas have been destroyed by over-cultivation. The average soil loss in Mashonaland is said to be a quarter of an inch a year. The underground water-level, it is said, has 'sunk dangerously low'.² In the extreme western part of the colony

¹ *Report of the Commission on the Financial and Economic Situation of Swaziland*, Cmd. 4114, 1932, p. 107.

² *Report of the Enquiry into the Economic Position of the Agricultural Industry of Southern Rhodesia*, 1934, p. 21.

overstocking has led to extensive soil loss from sheet erosion, and land that grew good crops of maize thirty years ago is now described as 'desert country' where farmers can no longer make a living. This condition is insidiously spreading east.

Erosion is also a dangerous element in the native reserves, where the population is increasing steadily.¹ Excessive overstocking exists in parts, and is aggravated by the increase in the bride-price which has taken place. Gullying has spread seriously during recent years, especially in Matabeleland. A potent cause is the wearing down of tracks made by the ox-drawn sleighs on which natives transport their own firewood and also the fuel for their European employers' tobacco flues.

Propaganda among European farmers in favour of anti-erosion measures started on a small scale in 1921. Few active steps were taken until 1929, when farmers began to protect their land by contour ridging. In 1931 the Rhodesia Agricultural Union appointed a Soil Erosion Committee whose report recommended the establishment of district soil conservation boards coordinated by a central soil conservation advisory council to advise the government on general policy. It also suggested that the Land Bank should increase facilities for loans for conservation works, that legislation should be amended so as to control veld fires and timber cutting, and that the Water Act should be extended so as to provide for the protection of catchment areas. The reduction of native stock, it stated, was a vital question, and it suggested that better facilities for the sale of cattle should be provided. Further recommendations were made by a committee which reported in 1934 on the economic position of the agricultural industry.² This committee recommended the building of small storage dams to hold up water, and also of larger irrigation dams, and suggested that the government should assist by making grants or loans on easy terms. It also recommended afforestation of catchment areas, and the extension of contour ridging on arable land.

Some progress in erosion control has been made. By the end of 1936, 1,597 miles of contour ridging had been done; it is assumed

¹ See Chap. XII, p. 809.

² *Report of the Enquiry into the Economic Position of the Agricultural Industry of Southern Rhodesia*, 1934, pp. 21-2.

that one mile of ridging protects 25 to 30 acres. At the present rate of progress about 3 per cent. of the total arable area is ridged annually. A Soil Conservation Act is under consideration. Free help and advice are given to farmers by government engineers, and government advances on easy terms are made for conservation and irrigation works. The Agricultural Department issues, free, limited quantities of Kudzu vine (which has been found useful for the quick revegetation of gullies in the United States), spineless cactus, and certain creeping grasses for planting in places where severe soil wash has occurred.

The Native Development Department now employs a soil conservation officer and a small staff of agricultural and erosion officers, who conduct propaganda in the reserves and supervise the construction of small conservation works. Efforts are being made to reach agreement with chiefs to divide the land into arable and grazing sections and forest reserves. A soil, vegetation, and land utilization survey of about 6,000,000 acres has been completed, and this has proved a useful guide to the erosive potentialities of different districts. The government has organized the construction of dams, weirs, and boreholes in the reserves. Up to March 1937 a sum of £138,154 had been spent on these activities. While the provision of more waterholes has relieved pressure on the land by permitting a more even distribution of stock, it has not by any means solved the problem, since cattle continue to increase. In spite of the active steps being taken, it is probable that in certain parts of the native reserves erosion is still gaining ground.

(f) *Northern Rhodesia*

Since the greater part of Northern Rhodesia is under savannah forest and bush, with only a small percentage of cultivation, and since between 50 and 60 per cent. is protected from overstocking by tsetse-fly, erosion is in the main a localized problem. In parts of the Southern Province, in particular, the introduction of ploughs has led to severe soil loss. The natives in this fly-free area are abandoning their old system of mixed cropping, which protected the soil, and ploughing up large fields in which maize is planted in rows. The soil is thus exposed, run-off is still further increased by the removal of stumps, and sheet erosion is the result. In the Central Province

and in a certain proportion of the native reserves the increase in the total area under cultivation is leading to a shortening of the period of bush fallow, and rapid deforestation is taking place.¹ Soil fertility is not generally high, and throughout the greater part of the country it is estimated that land can only be cultivated for two years and must then be rested for a number of years which natives were wont to put at twenty-five, but which must at all events be enough to allow for the restoration of forest growth. The population is unequally distributed, varying from over-concentration in some native reserves to a density of under 3 per square mile in other areas; it is in many districts already in excess of a figure which would allow much of the land to be rested for as long as is necessary.² In some places the growing of Kaffir corn, a particularly soil-exhausting crop, is causing rapid deterioration of soil.

In the north, north-west, and north-east of the territory, serious deforestation is occurring, partly as a result of changes in the traditional *chitemene* system of agriculture, some of which have resulted from European rule. Under this system, the native cultivator collects timber and brushwood from a wide area around his plot, and burns it on the land to be cultivated in order to obtain a fertilizing ash and to destroy weeds and insect pests. In the old days *chitemene* caused a certain amount of deforestation, but the usual practice was either to pollard the trees or to cut them down about shoulder- or waist-high, in which case they eventually grew up again. Owing partly to the absence of a large proportion of the able-bodied men in the mines, the natives, in some tribes at least, now chop down the trees altogether so that they cannot recover. Sometimes as much as 10 acres of forest may be cleared in this way to provide ash for one acre of cultivation. Large areas in the north-west have been reduced in this way from forest to poor scrub and grassland, showing signs of soil deterioration.³

No anti-erosion measures have as yet been taken by the government; but two agricultural research stations have been set up, one at Abercorn and the other in the Southern Province, where the question will be among the problems examined. An ecological

¹ *Annual Report on Native Affairs*, 1936, p. 16.

³ C. G. Trapnell and J. N. Clothier, *The Soils, Vegetation and Agricultural Systems of North Western Rhodesia, Report of the Ecological Survey*, 1937, p. 60.

survey of the north-western districts was recently completed,¹ and the information obtained should provide a basis for any future attempts at the use of land planning.

(g) *Nyasaland*

Erosion is regarded in Nyasaland as one of the most serious of the country's problems, particularly in the Shire Highlands, where the rainfall is generous but seasonal, and the population density high. Extensive deforestation on hill-sides has occurred; even in the last fifty years large tracts of forest have disappeared, and streams that used to flow regularly have become seasonal or even ceased to flow at all. It is said that this factor has rendered vast tracts of once fertile country uninhabitable, and that Nyasaland as a whole is now incapable of supporting one-half the population that it did one hundred years ago.² Though generalizations of this nature must be accepted with caution, yet the damage done is obvious. Important rivers, such as the Shire, have silted up; so much topsoil has been removed by wash that mountains and hills are now masses of bare rock, and once forested plains are treeless.

Certain of the Nyasaland soils are apt to form compact subsoil pans and crusts from which the topsoil is easily washed away. In the lowland areas there are frequent depressions, called *dambos* or *dimbas*, filled with fine soil particles washed down from the hills, and generally so waterlogged that cultivation is impossible without extensive draining. Measurements of soil loss from a newly cleared field on a 4 per cent. slope near Zomba, on red lateritic loam, showed that nearly 30 tons of topsoil were removed in a season.³ Steep slopes are everywhere under cultivation, and in a few places the population density is as high as 300 to the square mile. Soil loss is going on all the time, accentuated by such factors as the prevailing native custom of heating newly cleared soil in preparation for planting finger millet. On European farms erosion has taken a severe toll on tobacco lands, which have in some cases been reduced from a rich loam to a poor sandy loam by the placing of ridges and furrows for tobacco cultivation up and down the slope instead of along the contour.

Anti-erosion measures have been based upon the protection of

¹ *Ibid.*

² A. J. W. Hornby, *op. cit.*, p. 8.

³ *Ibid.*, p. 12.

the lowlands by reafforestation of the hills; but progress has been slow because reafforestation is expensive. No special organization has been created for erosion control, but efforts are co-ordinated by a Native Welfare Committee consisting of representatives of the different departments concerned. Forty-eight forest reserves have been scheduled on catchment areas, and natural vegetation within eight yards of the edge of the streams is protected in native areas. Native cultivation on steep slopes is in practice often prohibited, although there is no legislative basis for this action. In 1932 a Bush Fires Ordinance was issued to control burning, and to authorize penalties for those caught illegally starting fires; it has proved impossible in practice to stop bush fires altogether, but the damage is minimized by controlled burning carried out by the authorities before the traditional grass-burning season arrives.

Early in 1933 a committee of the Department of Agriculture recommended to the government (*inter alia*) that a stop should be put to the destruction of natural vegetation on steep slopes under the Forest Rules, that the cultivation of slopes with a gradient of more than one in eight should be prohibited unless terracing was first carried out, and that efforts be made to persuade the natives to reduce, and if possible abandon, the cultivation of finger millet. In addition, the government was urged to dig more wells so as to open up unoccupied land, and to appoint fire boards to settle the dates for the controlled early-burning of vegetation. In 1937, a Forest Officer, who had previously visited the United States to study methods of erosion control, was appointed for three years to supervise the application of land-use programmes in the Central and Northern Provinces.

(h) *Tanganyika*

The fact that the greater part of the territory is infested with tsetse fly has safeguarded large areas from damage by over-grazing; but where the tsetse area has advanced into cattle country, the resulting concentration of people and cattle in an ever lessening area has caused serious erosion. While tsetse in occupation of an area may preserve it from erosion, tsetse invading a hitherto uninfested area are a serious factor in causing erosion. The Director of Veterinary Services has estimated that 25,000 square

miles in the Lake, Central, and North-West Provinces are overstocked. He has put the carrying capacity of the available pastures at about 2,000,000 cattle and 2,000,000 sheep and goats, whereas there are at present 3,000,000 head of each of these categories of stock.

The government's tsetse policy has been to drive out the fly by clearing selected areas of bush, attention at the same time being concentrated on clearing corridors and barriers which open up the maximum area of new country with the minimum destruction of cover. The newly opened land is made over to native settlers, under conditions which will preserve the land and its water supplies.¹ Considerable acreages have been so treated. A solution of the overstocking problem by clearing more and more land of bush and opening up fresh water supplies can only be obtained if controlled grazing is practised in the new areas; if land were cleared of tsetse only to be over-grazed by stock the last state would be worse than the first.

Erosion is widespread on cultivated land, which only occupies, however, about one-thirtieth of the territory. The Central and Lake Provinces and the Kilimanjaro area are the most seriously affected. In the Central Province gullying is widespread, and some areas in the province are now rendered useless by it. In the Kilimanjaro area cultivation—largely of coffee—has replaced natural forest; the fertility of the once rich loam has been greatly reduced by soil wash, and recently the quality and yield of coffee has suffered. In the south-western part of the territory, round the Lupa gold-fields, land that was under cultivation sixty years ago is now barren and uninhabitable.² Experiments carried out at Mpwapwa, in northern Tanganyika (where the rainfall is 26 inches), showed an average soil loss over two seasons of 59·36 tons on a bare plot, whereas no losses at all from grass plots were recorded. The run-off from a bare, uncultivated plot was 55 times that on a grass plot.³

Recognition of the need for soil conservation came with the world depression. Up to 1929 crop yields, as a result of loss of soil

fertility, had been generally declining; but prices were high and profits satisfactory. With the fall in prices, attention became focused on the fall in yields. In 1931 an inter-departmental committee, set up to advise on the soil erosion problem, followed the example of Ceylon in holding that the first step must be to create a public opinion aware of the dangers and ready to co-operate in overcoming them. The Agricultural, Veterinary, and Education Departments joined in a campaign of propaganda on the subject. At the same time native administrations have been induced to enact rules making compulsory the adoption of anti-erosion measures. In eight districts (out of some forty-five) they have enacted rules covering all cultivations, while in two other districts rules have so far been applied to coffee only, which must be planted on land that has been terraced or contour-ridged. The native administrations in the Kilimanjaro area passed rules regulating coffee cultivation in 1932, following the concentration in the district of twenty-seven native instructors, equipped with dioramas, who spread propaganda and gave demonstrations. By the end of 1932, 1,200 new coffee plots had been planted in the approved (terraced) way. Rules have also been passed by the native authority on Mounts Kilimanjaro and Meru to prohibit cultivation near streams and to control grazing on the sides of the valleys. Communal reafforestation was begun here on a small scale in 1934. In the Lake Province a number of native authorities have passed rules for the preservation and rotation of grazing, for the protection of hill-tops and hill-sides from bush cutting and burning, and for the planting of trees. The native authorities in this province have also provided a number of dams, both large and small, and bore-holes. It is interesting to note that the text of the rules enacted by the chief of Usiha for the protection of trees on hills represents the chief as acting in his traditional role of rain-maker.¹ In the Iringa Province efforts are being made to control the burning of grass, and schemes of reafforestation and wind-break planting have been adopted by native authorities. The enlistment of the support of a number of chiefs and councils is considered to be a very important step forward in erosion control.

Forest rules were passed in 1933 authorizing administrative

¹ See E. Harrison, *op. cit.*, pp. 20-1.

officers to prohibit the destruction of trees on the upper slopes of hills and on the banks of streams. A survey of the relation between erosion and water supplies was carried out in 1935, and the need for the provision of new water supplies to open up uninhabited areas was stressed.¹ Experiments on a system of deferred grazing are being carried out in the Lake Province, where erosion caused by overstocking is particularly severe. Wind erosion has done severe damage in this province, and a policy of planting tree belts, launched in 1930, has established several hundred miles of wind breaks. Efforts are also being made to increase consumption of meat. A meat factory was established with government assistance at Mwanza, but at the end of some years proved unsuccessful.

At the experimental farms at Dodoma, Kandoa Irangi, and Singida demonstrations are carried out of the control and management of stock, and experiments are being conducted on the use of quick-growing manyara and sisal hedges, and on the value of groundnut tops for supplementary feeding of cattle. One of the problems in the Central and Northern Provinces is the concentration of population in the hills, where slopes are too steep for safe cultivation; recently a few settlements have been organized in the plains, with a small demonstration farm attached to each, in the hope that these examples will induce other natives to follow suit. In spite of such measures, however, erosion is still gaining ground in certain parts, notably where over-grazing exists. The Colonial Development Fund has given favourable consideration in 1937 to a request for assistance in carrying out a five-year scheme of water supply, forest preservation, and other anti-erosion measures.²

(i) *Kenya*

Erosion in parts of Kenya has reached an advanced stage. The Agricultural Adviser to the Secretary of State for the Colonies has stated that it is impossible to exaggerate the severity of the damage that has been done.³ This is, broadly speaking, of two types: sheet erosion and gullyng in the hilly agricultural districts of the

¹ See Chap. XV, p. 1044.

² See Chap. XV, p. 1045.

³ Sir F. Stockdale, 'Soil Erosion in the Colonial Empire', *Empire Journal of Experimental Agriculture*, vol. v, no. 20, 1937, p. 290.

highlands, and the creation of desert conditions in the arid and sub-arid pastoral districts at lower altitudes. The first type affects both European and native lands. On alienated farms erosion was allowed to proceed some way before its nature and causes were understood, and considerable loss of topsoil occurred from coffee and maize land. Yields of maize and wheat began, in places, to decline. As in Tanganyika, realization of the danger came with the world depression. As a result of propaganda conducted both by the Agricultural Department and by the Arbor Society, anti-erosion measures such as broad-base terracing, green-manuring, composting, and the retiring of steep slopes from cultivation are being taken on the European farms, though not yet on a scale sufficient to control erosion altogether. The obstacle in this case is lack of money rather than indifference. The Land and Agricultural Bank now permits advances to be made for erosion works on the security of the crop, but no assistance is given by government, as it is in South Africa, to farmers for anti-erosion work. Probably the most serious erosion on European farms is being caused by the stock of native squatters, which has increased enormously in the last ten years. Farms which were closed down or abandoned during the world depression were often taken over by uncontrolled native stock, over-grazed, and seriously damaged. An ordinance has recently been issued enabling squatter stock to be limited or prohibited in a district where a majority of the landowners vote in favour of such a course. The question has naturally been mooted, but not answered, of what is to become of the banned stock, should many of the districts take advantage of this provision; overstocking is already acute in most of the native reserves.¹

A survey of the underground water resources of the colony noted evidence of progressive desiccation during the past twenty years, and observed a tendency for perennial streams to become seasonal. Lake Rudolph has been falling at the rate of one foot a year for the past twenty-five years.² No general steps have yet been taken to prohibit cultivation on river-banks, or destruction of trees outside the forest reserves, nor has the government incurred direct expenditure in controlling head-waters or catchment areas.

A considerable amount of sheet and gully erosion has occurred

¹ See Chap. XII, p. 754.

² A. W. Champion, *op. cit.*, p. 107.

in parts of the Kavirondo reserve, where the acreage under export crops such as cotton and simsim is increasing year by year. The growing popularity of ploughs is another factor that has caused soil deterioration, and sheet erosion due to over-cultivation of slopes and over-grazing by goats is also occurring in the Kikuyu reserve. For the most part it is in its comparatively early stages and is therefore not plainly visible to the eye, but the number of *shambas* occupying steep slopes is such that its existence cannot be doubted. This reserve has suffered particularly from destruction of forest. A clue to the loss of topsoil which is occurring continuously on the cleared slopes of Mount Kenya is given by the heavy discharge of silt from the Tana river, which creates a brown stain in the Indian Ocean twenty or thirty miles out to sea. Measurements of the silt carried down by some of its small tributaries have shown that a storm may increase the load of silt fivefold.¹ In the lower-lying parts of the reserve, east of Embu, overstocking with goats and, more recently, cotton cultivation have caused such severe damage that parts of the Mbere District are now only fit to be abandoned.

It is in the mainly pastoral reserves of the Kamasia, the Suk, and the Turkana, and in the semi-pastoral, semi-agricultural reserve of the Wakamba, that the problem is at its worst.² Kamasia embraces a ridge of hilly and well-watered escarpment where cultivation is practised, sometimes on a slope of 70 per cent. or over. The lower slopes are given over to goats, who have reduced the vegetation to a little thorn and sansevieria and to a thin covering of weeds. The hill-sides are badly gullied.³ Excessive numbers of goats are carried, the average being 33 to each family; overstocking is, in fact, acute. The Suk reserve is entirely pastoral, except where vegetation has been totally destroyed and the land rendered useless. The carrying capacity, estimated at the rate of 50 acres to the beast, is put at 21,000 cattle only; the actual stock population is about 38,000 cattle and 135,870 sheep and goats.

The Ukamba reserve is divided into two sections, Machakos

¹ V. A. Beckley, *Soil Erosion*, Kenya Department of Agriculture, Bulletin 1, 1935, p. 8.

² See Chap. XII, pp. 811-12.

³ C. Maher, *Soil Erosion and Land Utilization in the Kamasia, Njemps, and East Suk Reserves*, 1937 (unpublished).

and Kitui, and both are notorious for the degree of erosion that has been reached. The Machakos reserve consists of a series of rolling ridges separated by gentle valleys; the tops of these hills were once forested, but they have now been stripped so bare that hardly a tree remains. Rainfall on the ridges varies from about 40 to 50 inches, so that drastic erosion occurs on bare or cultivated land. It is estimated that 37 per cent. of the Ukamba reserve, or 391,000 acres, has been eroded down to the subsoil and beyond.¹ The stock population of the Wakamba is now 250,000 cattle, 269,000 goats, and 50,000 sheep. The carrying capacity of their reserve was estimated in 1929 at a total of 60,000 head;² and since then it has declined. Every 3 acres now have to carry about 1 cow or ox and 2 goats. It has been estimated that about 50 acres should be allowed in the interests of the land. The Kitui reserve, unlike Machakos, is relatively flat and parts of it are semi-arid. The population has increased from 105,855 in 1921 to 152,584 in 1932; shifting cultivation is practised; the land has suffered accordingly, and famines are frequent. Cotton cultivation has recently been introduced, and sheet erosion has already reached the visible stage on most cotton plots. Overstocking is chronic, and water so scarce that cattle sometimes have to travel thirty or forty miles to drink. The hills are now bare of vegetation, badly gullied, and scoured by run-off.³

In recent years the government has become alive to the need for taking action in regard to the reserves, but it has not yet provided funds sufficient to deal with the problem on an effective scale. An Agricultural Officer has been seconded to make surveys of the badly eroded areas, and comprehensive reports of four of the regions have been prepared. In Kavirondo, nine small reclamation schemes have been approved by Local Native Councils, and a beginning has been made in checking the ploughing of steep slopes, building small dams, restricting cultivation on the edge of streams, and digging trenches or planting sisal and aloe lines along the contour of gentle slopes.⁴ In the Kikuyu reserve the introduc-

⁴ Sir F. Stockdale, *Report on his Visit, etc.*, op. cit., pp. 89-90.

tion of wattle¹ as a commercial crop has been a marked success, both as a cash crop and as a method of reafforesting the hill-sides and improving soil fertility. Mixed farming is gaining in popularity, the principal check to its spread being difficulties of land tenure. In one administrative district alone, however, there were recently estimated to be over 400 mixed farmers; almost every village is now provided with a compost-pit. The excessive and growing population of goats, which are extremely harmful to vegetation and (in rich areas such as the Kikuyu reserve) economically of negligible value, is still a problem which defies solution. The amended Native Authority Ordinance issued in 1937 authorizes headmen to give orders to control grass fires, and to prohibit grazing within areas closed to stock for reconditioning; headmen may also be empowered to call out able-bodied men for work on anti-erosion projects.

In pastoral areas the outlook is less hopeful. The live-stock population of the colony as a whole has more than doubled since 1920.² No large-scale attempts to limit stock or to institute systems of controlled grazing have been made. In Kamasia a Reconditioning Officer was appointed in 1930, and up to May, 1937 (about 6½ years), a total of £5,646 has been voted by the government, and £373 by the Baringo Local Native Council. (It is interesting to note that, during the last ten years, £9,308 has been spent by the government on famine relief in this reserve.) The method of reconditioning adopted is to close an area every year to all classes of stock, so as to enable the grasses to regenerate by natural seeding. Run-off on bare land is prevented by the digging of small trenches along the contour, and where the vegetation has been completely destroyed grass roots (Star and Kikuyu grasses) are planted by hand at the beginning of the rains. After two years a limited number of cattle are allowed back. Between 1931 and 1936, 9,500 acres had been reconditioned; the programme for 1936-7 involved 10,000 acres. The total area of the Kamasia reserve is 993,920 acres, of which it is estimated that 674,000 acres require reconditioning. Difficulty is experienced in the reconditioned areas in keeping the stock down to the figure allowed, and in stopping the trespassing of goats; and much

¹ See Chap. XIII, p. 890.

² *Report*, op. cit., Cmd. 4556, 1934, pp. 494-5.

damage has been incurred from premature or over-heavy stocking. The subsequent control of reconditioned land raises a problem that has not yet been solved, since it is obvious that the money spent will be thrown away if the land is again subjected to unrestricted stocking.

In the Ukamba reserve attention was first officially called to the progress of erosion by a memorandum submitted to the East African Commission by the Ulu Settlers' Association in 1924. The Agricultural Commission under the chairmanship of Sir Daniel Hall, which reported in 1929, urged immediate action, and recommended the compulsory culling of cattle.¹ The Kenya Land Commission of 1933 described erosion and overstocking in this reserve in very strong terms, and recommended that action should be taken without delay to introduce the culling of surplus stock and the control of grazing. The first action was taken in 1932, when 200 acres were experimentally stagger-trenched. In 1935 the Machakos Local Native Council engaged a Reconditioning Officer who treated 476 acres with stagger-trenching during the next two years; a further 200 acres were planted with Napier grass, and a total of 25,350 acres was closed to stock. In the past twelve years the Forestry Department has established just over 1,000 acres of trees (mainly gums) on the hill-tops. Less than 0.02 per cent. of the whole area is under forest reserve, in spite of the high proportion of hilly land. The possibility of opening a meat factory to buy surplus stock was first explored in 1927, and discussed at intervals for the next ten years. In 1937 Messrs. Liebig started building a factory in the Ukamba reserve capable of absorbing a maximum of 30,000 head of stock a year..

In the Kitui reserve expenditure on reconditioning has totalled £1,754 in the last ten years. In June 1936 the Kitui Local Native Council authorized headmen to call out able-bodied males for work on the closing of areas to stock and on stagger-trenching. In 1936 a scheme for the reconditioning of the whole Ukamba reserve was drawn up by an officer especially seconded to make erosion surveys, and application was made to the Colonial Development Fund for a grant to finance it. In November 1937 a sum of £34,000 was made available, £10,000 as a grant, and £24,000 as

¹ The enforcement of destocking measures has led in 1938 to protests from the natives.

a loan, to the Local Native Council. The work will be carried out by the newly formed Soil Conservation Service of the Department of Agriculture. The Kitui reserve embraces about 250,000 acres infested with tsetse fly, and part of this will be opened up.

Widespread erosion due to overstocking also exists in parts of the arid Northern Frontier District, which occupies nearly half the colony. The Turkana desert south-east of Lake Rudolph is said to be advancing eastwards, and wind erosion is severe. Trampling, around the few and scattered wells, has created ever-widening circles of complete desert. The administration is attempting to provide new water supplies by building shallow dams to hold rain water, which is at present almost wholly wasted.

(j) *Uganda*

It is only recently that the existence of insidious and fairly widespread sheet erosion in Uganda has been recognized. Before the days of British rule, cultivation was scattered about in small patches in the bush and elephant grass, and little erosion occurred. The natives maintained soil fertility by mulching with banana leaves and split stems, and grew food crops in mixed stands so that the land was seldom without cover. The larger trees were rarely cut down. The introduction of cotton revolutionized the agricultural economy of the people. By 1936 some 1,500,000 acres were under cotton, and all of it represented new cultivation. Total acreage under food crops has also enormously increased, and the widespread introduction of ploughs has enabled the size of individual plots to be extended.¹

The worst erosion in Uganda occurs in the Eastern Province, especially in the Karamoja District near the edge of the Turkana desert. When Mount Elgon, on the Uganda-Kenya border, was first described in 1896, all its slopes were thickly forested; the forest is now shaved completely as far as the 7,000 feet contour line. The Karamoja region acts as a buffer between the desert and the agricultural regions to the west. Very severe overstocking exists. The grass is trampled out, the earth hard and impervious, and every rain storm pares the soil still further towards its bone.²

¹ W. S. Martin, *Agriculture and Agricultural Resources in Uganda*, Appendix A (unpublished).

² E. J. Wayland and N. V. Brasnett, *op. cit.*, p. 64.

The area as a whole is short of water, and a few wells have been drilled to secure the better distribution of stock. No control over the total numbers of stock in the district has, however, been attained, and it has been pointed out that a more even distribution without limitation of total numbers will only make matters worse, since the stock will increase to the limit beyond which the pasture will not keep them even barely alive.¹

In the Teso District, farther south, erosion on crop lands has arisen owing to a dense population and to the introduction of ploughs. The human population has increased from 266,000 in 1921 to 302,000 in 1936, and the cattle population has more than doubled since 1911. Cotton now occupies 158,900 acres, and there are over 15,000 ploughs at work. Ploughing—often up and down the slope—has largely superseded hand hoeing; clean clearing and the complete removal of roots and stumps has followed. The rainfall is irregular; the land suffers badly from desiccation during the dry season, and widespread sheet erosion has taken place. The practice of green-manuring, rotations, and slope-contouring is urgently needed.

Much forest has been destroyed by pastoral tribes in the past. The elephant grass that covers so much of Uganda is thought to be a secondary growth following the trees. Reafforestation is needed, especially in Karamoja. It has been stated that (partly no doubt as a sequel to forest destruction) the ground-water level is falling, and several lakes, notably Lakes George, Edward, and Kioga, are receding. This, in due course, is likely to lead to a slight but definite decrease in precipitation.

It is probable that no part of the protectorate is completely free from erosion damage. Gullying has reached a severe stage in the north, and both sheet and gully erosion is bad in the Ankole and West Nile Districts. In parts of the West Nile, where cotton is now extensively grown, heavy losses have occurred, and the soil has been described as a 'thin skin over quartz rubble'. Sheet erosion occurs in parts of the Buganda Province, where coffee and cotton are grown on slopes without terracing or contour ridging. Cotton yields are, in fact, beginning to decline, and quality has recently shown a tendency to fall off.

¹ E. J. Wayland and N. V. Brasnett, *op. cit.*, p. 53.

Government action was taken in July 1935, when an Agricultural Survey Committee, set up to deal generally with agricultural development, stated that no measures to restrict the increase of stock could be considered too drastic if soil erosion was the only alternative. A local committee, which reviewed the position in the Teso District, reported to the Survey Committee at the end of 1935, and as a result an Agricultural Officer has been posted to the district to organize such anti-erosion measures as involve no heavy capital expenditure. In 1936 an interim report was issued by the Director of Geological Survey and the Conservator of Forests.¹ Recommendations included an air survey of eroded areas, the demarcation and protection of all surviving forest and thick bush, the introduction of the weed *lantana* to provide cover, the drilling (where possible) of new wells, and a reduction of cattle in the Eastern Province and Ankole District. The writers of the report viewed with grave concern the debushing of parts of the country by the Veterinary Department in order to eradicate tsetse, since this—in the absence of any restriction on cattle increase—was merely an invitation to further erosion. A soil conservation scheme for the whole protectorate, costing £83,000 spread over ten years, was outlined. No indication has yet been given as to how far the government intends to act upon this report.

Experiments conducted by the Department of Agriculture have shown that fertility can be maintained by the resting of cultivated land for two or three years, at fairly frequent intervals, under elephant grass.² On coffee plantations, soil wash can be checked by laying elephant grass or banana trash along the contour, or by mulches of the same fibrous material. In the Eastern Province the widespread introduction of mixed farming, combined with broad-base terraces on slopes, is needed if the remaining topsoil is to be saved.

(k) *Sierra Leone*

Degradation of the original rain forest to bush and savannah has, according to some authorities, proceeded farther in Sierra Leone than in any other part of West Africa.³ Destruction of

¹ See above, p. 1058, note 3.

² See Chap. XIII, p. 962.

³ E. P. Stebbing, *The Forests of West Africa and the Sahara*, 1937, p. 3.

forest by shifting cultivation has been going on for a long time, but has been greatly accelerated recently by the growth of crops for export. Much of the country which was once forest-clad is now under secondary bush, and in the last few years a great deal of this bush has given way to cultivation.¹ The rainfall is high, and considerable loss of fertile topsoil has taken place. Coffee and other crops grown in the southern part of the territory have seriously deteriorated, and little terracing has yet been done; here the policy of the Agricultural Department is now declared to be to encourage terracing and mulching.

The northern part of the protectorate has suffered loss by the washing of soil from the undulating hills into the intersecting swampy valleys, where rice is grown. The chief problem here is the maintenance of soil fertility; many villages have been abandoned or considerably reduced in population owing to the deterioration of the soil. At the Njala agricultural station experiments are being conducted on green-manuring (for which the pigeon pea seems most suitable), and a search is being made for a quick-growing tree to plant on land reverting to bush fallow. The government has recently made a beginning in the demarcation of forest reserves with the object of checking further forest destruction, and is encouraging the growing of rice, which tends towards concentration of cultivation on level ground where erosion does not occur.

(1) *Gold Coast*

Over a million acres of land which were once under rain forest, the climax of growth in this region, are now under cacao. The forest is still receding. The clearance of forest has resulted in a general reduction of humidity in the cacao plantations, and this, combined with loss of soil fertility and of topsoil, has led to the dying back of cacao trees.² Soil loss has to some extent been held in check by the fact that the stumps of the forest trees have for the most part been left in the ground, thus facilitating absorption of rain water, and by the custom of growing food crops among the cacao trees. Even so, it has been stated that an

¹ F. A. Stockdale, *Report on his Visit to Nigeria, the Gold Coast, and Sierra Leone*, C.A.C. 270, 1936, p. 108.

² See Chap. XIV, pp. 1002-3.

active policy of forest conservation is needed if the cacao industry is to be saved from serious deterioration. Erosion is more serious where old forest land has been planted in maize, the principal food crop of the Gold Coast; large areas of maize land have now been stripped of their topsoil, and yields correspondingly reduced, especially near the coast.

The length to which soil deterioration has gone in this region was shown recently when an attempt to grow bananas for export from the port of Takoradi failed owing to the poverty of the soil, and the would-be growers were forced to go farther inland where virgin soil could still be found. In the northern part of the country the control of rinderpest has led to a rapid increase in stock, and over-grazing has recently become a serious problem. An attempt is being made to encourage mixed farming, and to persuade natives to grow cassava roots in order to feed their cattle during the dry season.

(m) *Nigeria*

Erosion in the Southern Provinces is to a large extent controlled by the traditional native system of cultivation, which is to grow crops on mounds made by throwing up the top layer of soil, so as to bury the weeds and grass;¹ in addition, mixed cropping is practised, so that the land is rarely left without vegetal cover. Investigation has shown this system to be sound, and the policy of the Agricultural Department is to foster it, and at the same time to discourage the introduction of ploughs unless mixed farming is practised and manure applied to the land. The spread of cultivation is, however, taking place at the expense of the forest, and this factor may in time have an injurious effect on the cacao plantations of the western districts. Already erosion has become serious in parts of the south-east provinces, largely because of the drastic shortening of the period of fallow, and gullies 100 feet deep are not exceptional in hilly regions.

In an earlier chapter, reference was made to differing views held on the question whether the Sahara is advancing into North Nigeria.² In one sense the Sahara is undoubtedly advancing; the land on its borders is suffering from an increasing degradation.

¹ See Chap. XIII, p. 880.

² See Chap. I, p. 14, and Chap. XIV, p. 999.

Not only is grass being killed by excessive trampling and by burning, but such trees as have managed to adapt themselves to the arid conditions are repeatedly pollarded in order to provide food for goats, and in this way weakened and killed. Fine sand blown from the north by the seasonal harmattan is a factor, although not the major one, in deteriorating soil conditions. Doubt has been expressed as to whether the careful and industrious system of agriculture practised around Kano can survive for much longer, if destruction of vegetation continues at the present rate. In the Southern Sahara itself there is evidence that rivers have dried up, and the water table—which is now 50 feet or more beneath the surface—has fallen within the last two or three centuries. North of the Anglo-French boundary, territory that is now true desert was fairly closely populated until well into the eighteenth century; it has been stated that: 'it has only taken some 200 years to depopulate a country as large as the Union of South Africa.'¹ It is a natural assumption that destruction of such vegetal cover as exists farther south, if allowed to continue, may have the same effect.

An Anglo-French Commission was recently appointed to collect all available data on the progress of desiccation along the Niger-Nigeria border, and on the causes of the spread of desert conditions.² This commission, consisting of three French and four British members, examined the situation on the spot from December 1936 to February 1937. It reported that trees had suffered severely from shifting cultivation, and that sand, borne by strong east winds blowing at the beginning of the rains, had frequently destroyed germinating crops by burying them. It recommended the establishment of shelter-belts at right-angles to the winds and of hedges or lines of trees to mark farm boundaries, and the creation of tree plantations.

South of the Sahara fringe, but still in the Northern Provinces, signs of soil exhaustion due to the continuous planting of cotton and groundnuts, to the shortening of the period of fallow, and to veld burning, are becoming apparent. There is evidence that this

¹ Empire Forestry Conference, South Africa, 1935, *Report of the Committee on Forests in relation to Climate, Water Conservation and Erosion*, p. 25.

² *Report of Anglo-French Forestry Commission, Nigeria-Niger, Dec. 1936-Feb. 1937.*

region was once much more thickly forested than it is at present. Erosion is most severe in the 10-15-inch rainfall belt, where the hot, dry season, when the harmattan blows, is followed by torrential rains. In the north-west the situation is being aggravated by the flow of population from the French colonies, following recent tax reductions in Nigeria, which is leading to bush destruction and to soil deterioration. Mixed farming is now believed to be the sovereign remedy for soil depletion.¹ Green-manuring has been tried, but has proved a failure owing to the length of the dry season.

Farther south extensive clearing of forest has taken place, the trees having been replaced by coarse *cymbopogon* grass; and an area which used to be regarded as the granary of the south will now produce a considerable surplus in favourable seasons only. Fertility is gradually falling, and there is a danger that the deterioration may be progressive so long as the population increases. Measures taken to arrest this tendency include the importation of a small herd of Gold Coast cattle, partially immune to tsetse infection,² as part of the policy of encouraging mixed farming, and experiments with green manure and cover crops. It is hoped, with the use of such crops, to be able to reduce the period of fallow without also reducing soil fertility. The Forestry Department is reclaiming a badly gullied part of the Udi plateau in Southern Nigeria by prohibiting grazing, checking fires, building small dams at the heads of gullies, and digging staggered trenches along the contour on sloping land.

(n) *Problem of Soil Erosion in the Territories of the other Colonial Powers*

It is recognized in the French colonies that the introduction of measures to stop wholesale firing and to control shifting cultivation is essential; and that though rules have been drawn up on the subject of these practices their introduction must be a delicate business. The rules have been introduced into the Cameroons, and the benefits are said to be already becoming evident.³

In the Niger Colony and French Sudan the forest is of the

¹ See Chap. XIII, p. 963.

² See Chap. XIII, pp. 933, 976.

³ J. Méniand, 'Rapport succinct sur la politique forestière poursuivie dans les colonies françaises—résultats obtenus depuis 1926', *Actes, II^e Congrès International de Sylviculture*, 1936, vol. iii, pp. 655-7.

savannah type subject to shifting cultivation. Annual firing and the strong winds of the dry season are making the savannah more and more open; the covering layer of sand on the soil increases in thickness, and the open savannah degenerates into thorn bush and, lastly, tufted grass masses. With the disappearance of the latter full desert conditions are achieved. There is no forest staff in these colonies and no protective steps appear to have been introduced, but the joint Anglo-French Commission, to which reference has been made, has studied the problem.¹ In the Gabon fears have been expressed that the practice of shifting cultivation may gravely injure the forest growth, but steps do not seem to have been taken to deal with the matter.² There has been a serious deterioration in part of the lands producing groundnuts in Senegal, but it is doubtful if this was due to erosion, or merely the result of overcropping.

The effects of serious erosion are observable in the Belgian mandated territory of Ruanda-Urundi, and there is reason to believe that similar problems face the administrations in parts of the Portuguese territories. It might well be that an investigation into the question of erosion in these territories would yield interesting results. The effects of erosion are, on the other hand, less observable in the Belgian Congo, but the government has already begun to take measures to prevent it, notably the constitution of numerous forest reserves and a rigorous application of the decree concerning the cutting of wood in Crown forests.³

The Belgian *Ministère des Colonies* has published an admirable pamphlet on soil erosion, based mainly on experience and experiments in British territories.⁴

V. CONCLUSION

There are certain difficulties inherent in a study of soil erosion, whether in Africa or elsewhere. It has been made clear⁵ that the term has here been used throughout in the sense of accelerated erosion, due to the action of man. But it is never easy to distin-

⁵ See above, p. 1056.

guish the damage due to the direct action of man from that which natural forces must inevitably occasion. The task is all the more difficult when the area under observation is, like the greater part of Africa, one of unstable climatic equilibrium. There is always the danger that the observer may be led to regard as due to man, and therefore capable of redress by him, matters for which there is, in the nature of things, no ready remedy. In the particular case of Africa a survey of the extent of erosion, consisting as it does of a summary of unrelated expert opinions, cannot be regarded as a scientifically objective statement. Erosion may appear, from the evidence, to be a serious problem in one territory and of little significance in another; but this impression may be largely a result of the greater interest taken in the subject in the one territory than in the other, which may in turn be traced to the personality of the officers principally concerned. Nor can the efficacy of the anti-erosion measures taken in different territories be fairly compared from the evidence available. Propaganda among natives, for example, is a method employed in many government campaigns, but its value depends upon the weapons used; it may be worthless; on the other hand, if energetically handled, it may be very effective. This summary can only be regarded, therefore, as a rough guide to the subject.

Even so, certain facts clearly emerge. The first is the widespread nature of the problem. Hardly a territory is free from the threat or the reality of erosion in one form or another. A second point which arises is the need for factual surveys of soil conditions, types of vegetation, extent of stocking, and the agricultural customs of the people, in order that a clear picture may be obtained of the extent to which soil deterioration has already proceeded, and of the factors making for its acceleration or the reverse. Only on the basis of such concrete information can a sound policy of soil conservation for any particular area concerned be evolved; for, while the principles are the same everywhere, the practice must vary widely according to soil, climate, the use to which the land is put, and the customs of the people who inhabit it.

The survey will vary in value for different territories, since the range of potential damage from erosion, and the form in which the damage may come, also differ widely. The problem has a very

different aspect on the Belgian Congo and in East Africa. But there can be no territory which can afford entirely to neglect it, for soil conservation is of universal interest in Africa. Except in the regions where minerals are of predominant importance, the wealth of the African people can be derived only from the soil; if the soil fails, then the ideals of African advancement must fail too.¹ A rising standard of living cannot be based upon a falling level of soil fertility. In most countries of Europe, where the maintenance of fertility is taken for granted, soil is generally regarded as a fixed and constant element in a changing world. This attitude is a dangerous one when applied to Africa, because the assumptions on which it is based are false. Tropical soil is not constant, it is changing always; easily destroyed, only time can recreate it; unwisely treated, it will cease to yield its harvests in a very few years.

The main conclusions which emerge from the material set out in this chapter would seem to be that in no territory where erosion has become severe do the measures being taken appear to be adequate to reverse the process; and that, in spite of much that has been done, no co-ordinated policy has yet been formulated for the British African dependencies. Though conditions vary from place to place and must be independently studied, the main lines of any conservation policy must be the same throughout tropical Africa. A falling water-table on one side of a boundary is a matter of concern to the neighbouring administration, as also are such erosive factors as blowing sand and flooding along river valleys. It is, therefore, a matter of urgency for the various governments in Africa to correlate their policies. There appear, however, to be considerable differences in the extent to which regulations regarding such matters as veld-burning or protection of forests and water supplies are at present applied. No territory has yet adopted a soil conservation ordinance dealing with the matter in a comprehensive way. Nor has the question of development in relation to conservation been sufficiently considered. It was the fashion half a century ago to regard the resources of Africa as 'unlimited'. Now it is realized that not only are they limited, but that the limits are

¹ See *Report of Commission on Higher Education in East Africa*, Colonial 142, 1937, pp. 14, 16.

lower than was at first supposed. Questions such as how far development can be pushed without overstraining the capacity of the land are beginning to arise, and it is clear that, if development is not to be wasteful or even harmful, they will require serious study. These matters also bear an interesting relation to the questions of land tenure discussed in the second part of Chapter XII; it will in particular be necessary to consider how far subdivision may safely be pushed before the point is reached where the land unit is too small to support a family without deterioration, having regard to the apparent need of African soils for periodic rest.

The central element in soil conservation is, as has been stated, the maintenance on the land of sufficient vegetal cover to prevent damage by wash and wind, and to safeguard water supplies. In Africa this resolves itself into four main problems: the preservation of existing forests and the afforestation of steep slopes and hill-tops;¹ the control of overstocking and the application of scientific pasture management;² the protection of water supplies;³ and the reorganization of native agriculture, so as to extend mixed farming where possible, and to protect cultivated land by terracing, cover crops, green-manuring, strip-cropping, and other means.

The main obstacles to the solution of these problems are two in number: lack of money and lack of African co-operation. The first is mainly a local problem, although help from the Colonial Development Fund has been forthcoming in several territories.⁴ Each country has to classify the claims on its revenues according to its most fundamental needs, and, as was remarked of the question of water supply,⁵ the claims of soil conservation are certainly not less than those of some of the social services which now engage a large share of public expenditure. The second is one of the most difficult problems in the complex question of soil conservation. There are certain aspects of soil erosion work in which the state can take direct action, as, for example, the reservation of forests, or the execution of large conservation works at the head of rivers. But if a remedy is to be found for widespread mischief such as the

¹ See Chap. XIV, pp. 984 ff.

² See Chap. XIII, p. 971.

³ See Chap. XIV, p. 984.

⁴ See below, p. 1113.

⁵ See Chap. XV, p. 1052.

deterioration of soil or pasture, a vast mass of individuals must co-operate in the work, and their share in it will often involve them in much additional labour and the sacrifice of immediate profits. Governments will seek by various methods to obtain this co-operation. The French will look to the influence of their chiefs, who are now gradually taking the character of a body of trained native assistants.¹ Both France and Belgium will have at their disposal the methods of 'educative cultivation'.² The British administrations will use the services of the 'native administrations', and have, indeed, as has been shown, already begun to do so on a wide scale. But none of these agencies can in the long run be effective unless the conviction is widely spread in African society that soil conservation is for the benefit of the individual more than for that of the state.

Some observers have doubted whether the quality of propaganda now carried on by certain of the British territories is sufficiently well organized. At present such propaganda is one of many duties performed by Administrative Officers, by Agricultural Officers, and by native members of agricultural staffs; but it is made less effective by the small proportion of both Administrative and Departmental Officers who really know the local languages. In a few territories (e.g. Kenya and Tanganyika) the subject is being introduced into native schools. With the exception of the issue of posters in Swahili by the Kenya Arbor Society (an unofficial body), the showing of a soil erosion film in East Africa, and a projected experiment in vernacular broadcasting in Kenya,³ and some slight use of the native press,⁴ it has not been found possible to make much use of modern methods of propaganda. Further activity is clearly required, though it must be realized that at present only a limited use can be made, for this particular purpose, of the methods of propaganda used in civilized countries. The public which has to be reached is one of cultivators and pastoralists; to most of them the cinema and similar devices represent an alien and unfamiliar world, and the lessons conveyed by these means do not always strike them as relevant to their own circumstances. The task of persuasion will necessarily

¹ See Chap. IX, pp. 484 ff.

³ See Chap. XVIII, p. 1300.

² See Chap. XI, pp. 630 ff.

⁴ See, e.g., *Mutende*, no. 24, Feb. 1938, p. 10.

be a long one; but the most persuasive argument is, and will continue to be, an ocular proof of the benefits which the use of the new methods can ensure. That the lesson is not an easy one is shown by the difficulties encountered by the Union scientific departments in dealing with their European farmers; with the African native the difficulty is all the greater because measures considered necessary to conserve soil in some cases involve fundamental changes in his customs and outlook. The attitude of pastoral Africans to their stock, the need for the replacement of live-stock by money as the medium of exchange, and possibly alterations in native land tenure involving the introduction of individual tenure, are obvious examples. Some reference has already been made to the lack of attempts made to approach these problems from the anthropological or psychological point of view, although they are fundamentally problems of native social structure and psychology.¹

Even with more extended propaganda, however, and with the anthropologist's help, one exceptionally difficult problem is likely to remain. It is doubtful whether pastoral natives could, in general, be persuaded to acquiesce in the voluntary reduction of their stock. The herdsman is, almost universally, more conservative and more tenacious of his point of view than the agriculturist, and the deeply ingrained habit of reckoning wealth in terms of stock is unlikely to yield quickly to propaganda or advice. Meanwhile the mischief done by overstocking is cumulative, and governments in certain areas must face the question whether stronger methods of persuasion should be used, and, if so, how they could be applied. Such possibilities as a progressive stock tax rising with the animal's age, and of erecting meat factories and compelling the sale of a proportion of herds over a certain size to the factory at a fixed price, have been considered, and each has its own difficulties. No government would embark on a policy of compulsory reduction of stock except with the gravest reluctance. On the other hand, the fact cannot be denied that in some areas the land cannot be prevented from complete degradation into desert unless the pressure of stock is relieved. A point apparently deserving special consideration is the rapid increase of goats. These animals are

¹ See above, p. 106g. -

seldom used extensively either for food or for any economic purpose; and in some areas they have destroyed vegetation completely and caused the worst forms of erosion.

The protection of water supplies, vital to Africa's future, is now recognized to be bound up with the restoration of forest and grass cover to hill-sides and crests. Forest policy in the African dependencies is discussed in Chapter XIV. From the point of view of erosion, a more active policy of afforestation seems needed. A considerable lack of uniformity exists in the legislation framed to protect springs and streams. The enforcement of some general minimum standard of care by passing laws or regulations (where they do not as yet exist) on the lines already laid down in some territories, prohibiting cultivation or grazing within a certain distance of all streams, and controlling fires on watersheds, might prove practicable. Something has already been said elsewhere of the need for a more thorough investigation of the underground water resources of certain areas.¹ The building of small earth-dams to control the head-waters and upper reaches of rivers, on the lines developed in Basutoland and South Africa, is another method which holds possibilities for other territories. The question of how far the provisions which exist in many African territories for the calling out of native labour on works intended for the public benefit can be used in regard to soil conservation measures appears also to be worthy of consideration.

The needs of soil conservation, which have only been generally discussed in the last few years, have not yet been reconciled with policies which were in operation before conservation was regarded as a major problem, and were, therefore, framed without consideration of the dangers of soil erosion. Contradictions can be traced in the policies of various territories. On the one hand, there is the desire to increase production as quickly as possible in order to raise the standard of living of the people; on the other hand, is the fear that, if expansion of cultivation outstrips the spread of conservation measures, permanent loss of soil fertility and the ultimate impoverishment of the people will result. On the one hand, veterinary scientists control stock diseases with a resulting increase in the numbers of inferior cattle; on the other

¹ See Chap. XIV, p. 1026.

hand, District Officers find in many places that pastures are being destroyed wholesale. At one moment the introduction of ploughs may be urged, at another ploughs may be condemned as causing erosion; in one area the clearing of tsetse bush is regarded as an urgent health measure, in the next tsetse is regarded as the preserver of bush and hence of water supplies; in one region the cultivation of cotton is regarded as the key to progress and prosperity, in the next it is accused of destroying the fertility of the soil. These and other incipient contradictions can only be resolved by interdepartmental and interstate consultation, and by co-operative planning.

It is to be regretted that there is in Great Britain no one body which can deal specifically with the range of questions arising in connexion with the problem of soil conservation in Africa. There is, however, an increasing interest in the subject, to which the extensive journeys of the Secretary of State's technical advisers have repeatedly called attention.¹ The only fund at the disposal of the Colonial Office for this purpose, the Colonial Development Fund, has been used in growing measure to finance anti-erosion measures. Whereas in the first seven years of the fund's existence, up to March, 1936, only 10 per cent. of the moneys had been devoted to land reclamation, drainage, and water projects, in the year 1936-7, 36 per cent. of the money voted, amounting to £293,643, went for these purposes.² In the eleven months ending February, 1938, £234,120 went to land reclamation and water measures in Africa. The value of this assistance would be enhanced if an expert inquiry could now be initiated, which would deal with all the areas most seriously affected, and form the basis of the interdepartmental consultations, or the interstate discussions which, as suggested above, are required in order to formulate a co-ordinated scheme of action.

CHAPTER XVII

HEALTH

It has already been stated that Africa supports a relatively small population at a low subsistence level. As might be expected, this fact is closely linked with the physical condition of the people; the problem of health is, indeed, in a great measure the problem of subsistence. Public attention and public sympathy, from the days of Livingstone onwards, have been concentrated upon the grave diseases such as leprosy, sleeping sickness, and malaria, from which in Africa there is widespread suffering, and alleviation of these sufferings has been the prime object of medical aid and of public philanthropy. The realization of another approach is rapidly gaining ground.

'No preventive campaign against malaria, against tuberculosis, or against leprosy, no maternity relief or child welfare activities, are likely to achieve any great success unless those responsible recognize the vital importance of this factor of defective nutrition and from the very start give it their most serious consideration. . . . Abundant supplies of quinine, and the multiplication of tuberculosis hospitals, sanatoria, leprosy colonies, and maternity and child welfare centres are no doubt desirable, if not essential, but none of these go to the root of the matter. The first essentials for the prevention of disease are a higher standard of health, a better physique, and a greater power of resistance to infection.'

These passages are quoted from the annual report of the Public Health Commissioner of the Government of India for 1935; but they might with equal truth have found a place in the annual health report of any African territory.¹

It is this fact, above all others, which seems to determine the position which the health services now occupy in the general organization for the development of native welfare in Africa. Important as may be the influence of nutrition on health conditions in Europe, it does not exercise the same decisive effect on the factor of resistance as in Africa. Medical science must be in Africa increasingly concerned with the relations between nutrition and health, and with advising on the medical aspect of social policies

¹ See, for example, Kenya, *Medical Department Annual Report*, 1922.

bearing on the question of subsistence. In the second place, the fact that there is one widely prevalent factor which, by reducing the power of resistance, favours the widespread existence of disease, suggests the conclusion that the methods applied by health services must be largely those of mass attack. The preventive treatment applied to certain of the African diseases, to be effective, must partake to some extent of the character of an operation, scientifically planned and humanely conducted, but military in its spirit of offensive and in the thoroughness with which it establishes itself in the area it has occupied. There is a third point; the narrowness of the financial resources available, which in Europe would appear almost derisory in view of the scope of the operations to be undertaken, requires that, under a scientific leadership, there should be a large body of assistants, who must as far as possible be Africans, and who must have as complete a system of training as circumstances will permit. The scope of activity of the health services in Africa is not, therefore, confined to the application of the lessons which modern science conveys of the causes of disease or the method of relieving it. There is added to that the task of organizing to the best purpose the narrow resources which the state can place at their disposal, the education of Africans to take part in health activities, and the co-operation with the other social services whose work lies in the betterment of African conditions of life.

I. THE BEGINNINGS OF MEDICAL WORK IN AFRICA

The Franciscan missionaries in Angola discovered in 1774 the ruins of a hospital built by the Capuchins, who occupied the territory in 1640; this appears to be the first recorded instance of medical work by Europeans south of the Sahara. The first qualified medical missionary of the Protestant churches was probably Dr. Vanderkemp, who offered his services to the London Missionary Society in 1795. In 1810 he completed a 'considerable book on midwifery' for the benefit of the Hottentots, among whom he worked at Betheldorp, near Algoa Bay.¹ The Moravian missionaries were also early in the field, and in 1823 they undertook the supervision of a leper colony at Hemel-en-Aarde, Cape Province.²

¹ A. D. Martin, *Doctor M. Vanderkemp*, 1931.

² J. E. Hutton, *Short History of the Moravian Church*, 1895.

It was not, however, until David Livingstone had captured the imagination of Europe and America that medical missionary work was established widely. Livingstone felt impelled to devote his life to the 'alleviation of human suffering', and set himself to obtain a medical education before offering himself for work in the mission field. He sailed for Capetown in 1840. In his diaries he noted the diseases prevalent among the tribes he visited. He commented on the inadequate surgical knowledge of the native doctors, and listed twenty-seven 'medicines' employed by natives.¹ His mind was much occupied with the nature of 'African fever' and the way to cure it. In 1859 he sent to Sir James Clark, M.D., in London, a report on the treatment of malaria, giving the details of many cases, the remedies administered, and their effects.

A year after Livingstone sailed for Africa, interest in the work of Dr. Peter Parker, an American medical missionary on furlough from the Far East, led to the founding by Dr. John Abercrombie of the Edinburgh Medical Missionary Society, an institution for training medical students, on graduation, for missionary work.² In South Africa the Lovedale Missionary Institution, Cape Province, was founded by the Scottish Presbyterians in 1841, and the Victoria Hospital, which is part of the Institution, was established for the treatment of disease and for the training of native nurses, hospital attendants, and dispensers. In 1847 the Society for the Propagation of the Gospel began medical work at Colesberg in South Africa. It is noteworthy that in 1849 there were only forty medical missionaries at work in the whole world.³ At a later date the American Mission Board in Johannesburg was a pioneer in the establishment of native health centres on the Reef, and also established the Bridgman Memorial Hospital, the only native maternity hospital in Johannesburg.

Medical missions in East Africa appear to have begun with the association of a lay doctor with the Holy Ghost Fathers at Zanzibar in 1863. The Universities Mission to Central Africa began work in the Shire Highlands in Nyasaland at about the same time, but moved to Zanzibar in 1865 and opened a hospital there

¹ D. Livingstone, *Missionary Travels and Researches in South Africa*, 1857, pp. 647-50.

² *A Brief History of Missionary Enterprise*, Burroughs Wellcome & Co., 1910.

³ H. O. Dwight, H. A. Tupper, and F. Bliss, *Encyclopaedia of Missions*, 1904.

in 1887. Many of the ordained missionaries of the United Free Church of Scotland and of the Established Church of Scotland were fully-qualified medical men. These missions considered that a medical officer should be appointed to the staff of every station in Africa, for the benefit of the Europeans and to train Africans for medical work among their own people. Work was begun at Livingstonia in 1875 and in the following year at Blantyre. The year 1875 witnessed also the beginning of medical work by the Church Missionary Society at Mombasa. In 1893 a hospital with fifty beds was built, and later a leper house was added.¹

West Africa had a very sinister reputation in the matter of health. The early explorers were almost wiped out by disease.² Of the first company of eighty-eight freed slaves and three Europeans which set out for Liberia in 1818, all the Europeans and many of the negroes died within a few months; at a later date, of a shipload of 105 all contracted fever within a month and many died.³ In 1832 three missionaries of the Basle Mission, one of whom was a doctor, reached the Gold Coast, following on an earlier mission of 1828 whose members had all perished, and the first medical missionary of the Church Missionary Society arrived in Sierra Leone in 1892.

In the absence of any knowledge as to the cause or cure of tropical diseases, the work of the earlier medical missionaries in Africa must often have seemed hopeless. The mortality among Europeans was very heavy. From 1835 to 1907 the Wesleyan Methodist Missionary Society sent out 225 missionaries to the West Coast, of whom 62 died in the field.⁴ Of the Baptist missionaries in the Belgian Congo in the decade 1878-88, half died. It was, indeed, only when it was realized that biological agents were the cause of tropical diseases that an improvement could be effected in the health of Europeans in tropical Africa. A meeting of doctors convened by Dr. Harford-Battersby of the Church Missionary Society, in 1893, founded Livingstone College 'for the instruction of foreign mis-

⁴ Methodist Missionary Society, *West African Roll-Call*, 1907.

sionaries in the elements of practical medicine'. It was decided that no certificate would be issued to those completing the course, nor should students subsequently call themselves 'medical missionaries' or assume the positions of qualified medical men. The course included lectures in elementary physiology, principles of medicine, elementary anatomy and surgery, besides tropical diseases, and also attendance at hospital clinics. Of the 1,400 missionaries who have taken this simple course, 680 served or are serving in Africa. Their work has in many cases been acknowledged by governments, and some have received government grants in aid of drugs and dressings. Certain missionaries in the Congo who have taken the Livingstone course have been asked by the Belgian and French Governments to undertake surveys with reference to the incidence of sleeping sickness, leprosy, and yaws.

Dr. Howard, who arrived in Nyasaland in 1899, was a pioneer of the new methods. He determined first to secure healthier living conditions for Europeans, but he also organized medical services among the natives, and the Nyasaland diocese established in due course a hospital and surgery on almost every station.¹ The belief that the excessive mortality among missionaries might be prevented if the newly discovered laws governing tropical diseases were better understood and applied prompted the dispatch by the Wesleyan Methodist Missionary Society in 1901 of a commission to West Africa to investigate conditions of housing and health, and to frame regulations for guarding European health and life along the coast. The Society's attention was directed to medical work among the natives in West Africa in 1904, and in 1912 a hospital was built at Ilesha in Nigeria.²

There has also been considerable extension of the medical work done by the Roman Catholic missions. The White Fathers, to whom was entrusted in 1878 the task of evangelizing the area round the Great Lakes, and whose work now extends into the Belgian Congo, Northern Rhodesia, and Tanganyika, receive medical training during their novitiate, and the care of the sick remains an invariable feature of their missionary work. In Uganda

¹ C. H. Wilson, *The History of the Universities Mission to Central Africa*, 1936.

² W. D. Holdsworth and G. G. Findlay, *History of the Wesleyan Methodist Missionary Society*, 1921, vol. iv.

also the White Sisters have since 1899 undertaken health work, and in 1935 had 5 hospitals, 10 maternity welfare centres, and 40 dispensaries. The Franciscans maintain hospitals and dispensaries in Uganda, the Belgian Congo, and elsewhere. The Fathers of the Holy Ghost, in West Africa, the Jesuits in the Rhodesias, the Benedictines in Central and East Africa and in the Belgian Congo, to mention only some of the more important religious orders, all provide some medical facilities at their stations, and maintain between them over 200 hospitals.¹ The number of fully trained doctors employed by the Roman Catholic missions is comparatively small; in 1934 there were said to be not more than 30,² and most of the medical work is done by a large number of priests and religious, trained in special courses in their countries of origin. The importance of health work is recognized by the Holy See, and a Papal Encyclical of 1936³ encouraged the training of women religious in midwifery and child welfare, with the aim of combating the high infant mortality in Africa.

As in India, the various administrations in Africa at first confined the provision of medical services to the needs of their own establishments. Only in some of the larger centres were the services extended sufficiently to provide hospitals or dispensaries for Africans. Perhaps the greatest single factor in producing a new attitude in the matter of health services for the native population was the impression created in Great Britain by the sleeping sickness epidemic in Uganda in 1901 and 1902. Various medical missionaries, including the White Fathers and the Church Missionary Society under Mr. (now Sir) Alfred Cook and his brother, were at work in the affected area. The epidemic assumed large proportions, and in March 1902 a missionary organization reported that in Kyagwe 14,000 deaths had occurred in twelve months. The Royal Society interested itself in the matter and sent out two commissions. It was estimated that 200,000 people had perished in the infected areas out of the 300,000 who originally dwelt there. In 1906 the Uganda Government came actively into the sphere of public health when Sir Hesketh Bell decided on the evacuation

¹ *Guida delle Missioni Cattoliche*, 1934, pp. 66 ff.

² *Ibid.*

³ *An Instruction of the Congregation of the Propagation of the Faith to Religious Institutes of Women regarding Assistance of Mothers and Infants in Missionary Lands*, Feb. 11, 1936.

of these areas. The public interest thus aroused in the health of Uganda received a further shock when in 1908 Colonel F. J. Lambkin reported that in certain areas the incidence of syphilis was as high as 90 per cent. Three officers of the Royal Army Medical Corps were at once sent to work on this disease, and from them as a nucleus the Uganda Government Medical Service rapidly developed.¹ The part taken by sleeping sickness in bringing the medical needs of Africa to the attention of Europe is further illustrated by the action of the Congo Free State in dispatching a mission to deal with sleeping sickness in the Congo in 1906; at a later date (1917) the situation in French Equatorial Africa moved the French Parliament to sanction a yearly grant of one million francs for medical assistance.

In the British West Coast dependencies medical services appear to have been generally neglected in the early days of settlement, and Mary Kingsley complained that 'no trouble is taken to pull the death-rate down by science'.² There were isolated medical officers, but the death-rate was high and candidates few. A committee, appointed after a deputation of merchants had waited on Mr. Chamberlain in 1901, recommended the amalgamation of the medical services on the West Coast, and this was carried out in 1902, when the West African Medical Service came into being.³

The foundation of Medical Departments in the other British colonies took place at about the same time; the various East African medical services were amalgamated in 1903, separated in 1908, and again amalgamated in 1920.⁴

As medical services improved, the confidence of the African in European medicine was gradually gained, and hospitals which were built originally for the use of sick officials have been enlarged into hospitals for the African population. The requirements of the Rand for African labour led to growing attention being devoted in Johannesburg to the scientific treatment of health conditions at the mines;⁵ the Germans showed their sense of the importance of the study of health questions by laying the foundation of a research service in their East African protectorate. In 1906-7 Dr. Koch

⁵ See Chap. XI, p. 673.

spent 18 months in East Africa on sleeping sickness investigations. A beginning was made in French West Africa with the scheme for the medical education of Africans, which now centres in the *École de Médecine* at Dakar, though the school itself was not formally opened until 1918.¹ The Great War had its own influence in the expansion of activity in health matters. While it brought large numbers of Africans into contact with European medical methods for the first time, it also opened the eyes of those responsible for recruitment of the natives to the vast amount of preventable disease, which led to the rejection of large numbers of recruits on medical grounds. The experience of the allied forces in the East African campaign furnished unhappy proofs of the wide incidence of physical disabilities, and the French experience of recruitment was responsible for a material alteration of the policy which expected to find in West and Equatorial Africa a reservoir from which large drafts could be drawn annually for the French army. Though as many as 181,000 'Senegalese' served at different times during the War, there is no doubt that there was among them an unusually high incidence of disease during their service in Europe;² and the physical condition of natives of Equatorial Africa has proved to be so low that little or no demand is now made on that territory for recruits.

Since the War there has everywhere been a very substantial expansion in the state health services. There was, in particular, a marked development in the Congo, where the demand for industrial labour revealed a grave state of physical disability in various areas, and the inquiries of the commissions appointed to investigate the subject resulted not only in a scientific planning of the health organization in the gold and copper mines,³ but the foundation of the great organizations for medical relief, the *Foréami* and the *Fomulac*, to which reference will subsequently be made.⁴ With the extension of the state health services there has followed in most African territories a large expansion of the hospital accommodation available for Africans and, in association therewith, the creation of out-patient clinics with satellite dispensaries in the surrounding country. In some British territories this development

¹ See below, p. 1185.

³ See Chap. XI, p. 680.

² See below, p. 1138.

⁴ See below, p. 1178.

has been assisted by the active co-operation of the native authorities, who themselves in many cases finance medical and health services in their areas. The hospital system has been augmented, especially in French and Belgian territories, by the creation of mobile units for dealing with outbreaks of epidemic disease¹ or for the application of preventive measures. There has at the same time been a great increase in the organization for research into African health questions, more particularly in the British territories, and, almost everywhere, a greater measure of attention to the need of increasing the facilities for the training of Africans to take a part, in various capacities, in the work of the health services, and to the need for popular education in hygiene.

II. THE PRINCIPAL DISEASES IN AFRICA

(a) *Nutritional Deficiencies*

Nutritional problems are now much in the minds of administrations: whether the African eats enough food and, if he does, whether it is of the right kind, and whether the attack on poor nutrition may not be the most important factor in reducing disease.² African food habits complicate the problem, for there are tribes which seem to maintain physical fitness on food which is, according to nutritionists, wanting in certain constituents essential to health. Further investigation into foods and dietary habits is required, and such inquiries might with advantage be associated with attempts to obtain more complete vital statistics,³ and with the work of sociological inquiries.⁴ As information accrues from the correlation of anthropological, agricultural, dietetic, and medical findings in a district, conclusions for that particular area may be expected to suggest new foods which could be grown to make up deficiencies in the customary local diet.⁵

⁴ See Chap. XXIV, p. 1620. ⁵ See W. M. Macmillan, *Africa Emergent*, 1938, p. 27.

Reports of food deficiencies have been received from almost every territory. In most places doubts have been raised as to the adequacy of the protein in the diet. Still more frequent have been reports showing that the African suffers from deficiency of vitamin A leading to night blindness and a pathological condition of the skin. Other reports have shown the existence of scurvy and pellagra, not as a rule in typical forms, but in those minor degrees which are just recognizable, yet which may have great influence on resistance to disease. Studies have been carried out in East Africa which show that African diet is deficient in calcium and rich in phosphorus, and blood tests have revealed a corresponding deficiency and excess of these minerals. Some relation between calcium deficiency and tropical ulcer has been shown to exist, and it is now generally recognized that this disease has a nutritional basis. In South Africa evidence given recently to the Native Labour Committee drew attention to the effects of nutritional deficiencies in the health of the native population, which it was asserted was deteriorating owing to this cause, while diseases such as tuberculosis were increasing.¹

Recent researches in West Africa point to the existence of poisonous elements in some diets. In Sierra Leone, for instance, it has been established that the disease formerly diagnosed as beri-beri, and ascribed to nutritional deficiency, was in fact caused by toxic matter in unwholesome rice.²

The nourishment of infants presents a special aspect of the problem. For instance, it is said that in some areas babies grow rapidly and strongly until they are weaned at the age of about 2 years, after which, through lack of milk, they become thin and bony and develop pot-bellies owing to excess of cereal food; while, on the other hand, infant mortality in the first months after birth is in other areas reported to be heavy, owing largely to irregular breast-feeding and the custom of giving infants sour porridge during the first week of life.

Only the fringe of the problem of nutrition in Africa has yet been touched. The British Colonial Office is now about to

¹ *Cape Times*, Feb. 4, 1938.

² W. A. Burnet, 'Report on Investigations into the Problem of Oedema', *Annual Report of the Medical and Sanitary Department*, 1931, pp. 81-117.

publish the results of a general inquiry undertaken on the advice of the Economic Advisory Council;¹ but in the British colonies themselves special inquiries appear to have been limited to those made in Kenya, Nigeria, and Tanganyika.² The British dependencies have not made the same study of labour dietaries as those carried out in the Rand³ and the Belgian Congo;⁴ it will be recalled that in the latter case a dietary is prescribed by law for all employed persons.

(b) *Malaria*

Three main types of malaria are recognized, corresponding to the three common varieties of malaria parasite which affect man, namely, *Plasmodium vivax*, *P. malariae*, and *P. falciparum*. The last variety is by far the most important in tropical Africa and in the low veld in South Africa. Malaria is widespread throughout Africa, with the exception of certain highland areas and the more southerly parts of the Union of South Africa, and it is often credited with retarding the development of both European and native populations in Africa more than any other single factor, and with responsibility for a high infantile mortality rate. On this latter point it is difficult to speak with any certainty, for, as already remarked,⁵ there is inadequate material on which to calculate the true incidence of infant mortality in Africa. In regard to control of the disease, different ideas prevail. On the one hand anti-mosquito measures such as drainage and oiling are advocated, and on the other, anti-parasitic methods such as the taking of quinine and other drugs. Recent entomological investigations have shown that there are varieties even of a single species of mosquito, and that one variety may act as invertebrate host for the malaria parasite while the other does not. As species and even varieties of anopheline mosquitoes often have different breeding-places, attempts have been made with varying success at species control, but it is still too early to say whether this method is effective.

Since the publication of the League of Nations' malaria reports,⁶

it has been generally recognized that appropriate measures to control the disease must vary from locality to locality. The Ross Institute, now incorporated with the London School of Hygiene and Tropical Medicine, has taken a leading part in advising malaria control measures in many parts of the world; its most recent achievement has been in connexion with the construction of the new Zambesi Bridge, where, as a result of planning hygienic measures before work started, scarcely a case of serious disease occurred among the European staff. Such measures cannot, however, be applied widely in rural Africa, though they may be very beneficial in urban areas, where the population is concentrated. As regards the treatment of rural areas generally, it must also be remembered that there are many parts of the world, formerly infected with malaria, where the disease has practically ceased to exist as a result of treatment and normal agricultural development; indeed, in many areas anophelines have remained common after malaria has disappeared. Even the elimination of malaria in townships in Africa by mosquito-control measures has raised its own problem, though one admittedly of a second order, in that Africans that live under mosquito-free conditions in these towns gradually lose their immunity, and are liable to acute attacks of the disease on their return to endemic areas.¹

In regard to the French colonies, Professor E. Marchoux has given it as his opinion that in most of the country the best approach to a solution of the problem is to cure the sick and improve the standard of living, and the general acceptance of this theory has furnished a stimulus to the execution of the policy of development associated with the name of M. Sarraut.² In the Belgian Congo information on the incidence of malaria has been collected during the past five years.³ The disease has been considerably reduced in townships in the Congo by anti-mosquito measures, the sanitary

service in some towns, and notably Élisabethville, being highly organized. The prophylactic use of quinine has been applied extensively in the mining areas and among native children in the areas under *Foréami*.¹

In South Africa and the British colonial territories anti-mosquito measures on a large scale have been confined to the main townships. Elsewhere steps have been taken to break the mosquito-man-mosquito cycle of the parasite in European homes by the use of mosquito screening, mosquito bed-nets, and the use of insecticidal sprays. Outside the large towns anti-malarial measures, except on some estates employing much African labour and in the compounds of large mines, such as those on the Rhodesian copper-belt, are usually confined to endeavours to raise the resistance of the natives by improved social conditions. In certain native areas in Natal Dr. G. A. Park Ross has instituted malaria control by the weekly spraying of native huts with a preparation of pyrethrum, a method which is said to be effective.

(c) *Blackwater Fever*

Blackwater fever is closely associated with malaria, and rarely occurs where anti-malarial measures are carefully carried out. The type of malaria parasite with which it is associated is *P. falciparum*, and its distribution, therefore, is the same as that of malaria due to infection with this parasite. The disease is rare in Africans, but there is an increase in cases, possibly owing to the loss of immunity already referred to; it is often seen in Europeans living in poor conditions.

Various theories have been put forward from time to time to explain the cause of the disease, but none has been conclusive. Professor J. G. Thomson, of the London School of Hygiene and Tropical Medicine, studied the disease in Southern Rhodesia, and summarized the knowledge then existing;² his work was con-

médical du Katanga, 1931, no. 4, 1932, nos. 1, 3; J. Schwetz, H. Baumann, Peel and Droeshaut, 'Sur la différence de l'infection malarienne, d'après l'âge, constatée chez les nourissons noirs de l'agglomération de Stanleyville', *Rivista di Malarologia*, vol. xii, no. 6, 1933, pp. 1147-54.

¹ See below, p. 1178.

² 'Researches on Blackwater Fever in Southern Rhodesia', London School of Tropical Medicine, *Research Memoir Series*, vol. vi, 1924.

tinued from 1925 to 1929 by Dr. G. R. Ross.¹ A marked advance in treatment was made by the introduction of blood transfusion. The disease is, however, still of importance in many parts of tropical Africa, and is in need of further study.

(d) *Yellow Fever*

Epidemics of yellow fever, another mosquito-borne disease, have occurred with a high mortality in North and South America and in West Africa. Outbreaks occur in both the French and British colonies in West Africa from time to time, Liberia being a permanent reservoir, from which the disease can be carried to adjoining territories. Investigation by officers of the Rockefeller Foundation has shown that in Liberia the majority of children contract the disease, though the mortality rate among them is only 5 per cent.

As the cases are sporadic and the symptoms ill defined and various, there may be large areas where, if South American conditions are duplicated, cases of yellow fever are undetected. Blood tests made in Uganda and the Sudan reveal that a number of adult Africans in those countries are immune from yellow fever, and, according to present knowledge, immunity can only be acquired through an attack of the disease. Hence in 1936 the Rockefeller Foundation collaborated with the Uganda Government in investigating the position in that country and in the Anglo-Egyptian Sudan, the main aim being to find clinical cases of the disease. The Human Trypanosomiasis Institute at Entebbe has been taken over for yellow fever research.²

Most of the survey work on yellow fever has been done by the International Health Division of the Rockefeller Foundation. Until 1934 a yellow fever laboratory was maintained at Yaba near Lagos, and this has since been taken over as part of the Medical Research Institute of the Nigerian Government, and is assisted by a grant from the Foundation. The work carried out by these institutions, together with the blood tests made on blood sera sent in for immunity tests from various parts of tropical Africa, has

¹ 'Researches on Blackwater Fever in Southern Rhodesia', London School of Hygiene and Tropical Medicine, *Memorandum* 6, 1932.

² See below, p. 1166.

enabled a provisional map to be made indicating the probable limits of the endemic area of yellow fever. This area includes territory extending, on the west, from the Gambia, Sierra Leone, Liberia, the Gold Coast, and Nigeria, through French Equatorial Africa, and the northern and central portions of the Belgian Congo, as far east as the south-western part of the Anglo-Egyptian Sudan, and Uganda.

Other countries, particularly India and South Africa, have become aware of the possibilities of receiving infection from aircraft, through the transfer of infected mosquitoes or persons from the infected areas to countries where yellow fever has not hitherto occurred. Precautions are, therefore, being taken to reduce risks to a minimum by the provision of anti-malarial aerodromes and by thorough disinfection of the aircraft. Discussion of the position has taken place at both the health conferences held in South Africa.¹ The International Convention for the Sanitary Control of Aerial Navigation of 1933, which was prepared by the Permanent Committee of the *Office International d'Hygiène Publique*, has recently been widely adopted. Positive results obtained by mouse protection tests are not always accepted as proof that yellow fever is present in the 'silent' areas, and this emphasizes the need for proving the presence of clinical cases in these places.

In some of the towns where the disease has occurred, measures are taken for reducing mosquitoes. There are some notable examples of success; thus Freetown, in Sierra Leone, where yellow fever was prevalent, has had few cases since the introduction of a piped water-supply more than twelve years ago. In spite of all precautions there have been some calamities, notably the epidemic in Bathurst in 1934. In this outbreak the infective zone was in the European residential area, and subsequent investigations showed that the reported cases were but a fraction of those which must have occurred.

Preventive inoculation, started in America by Dr. W. A. Sawyer and his collaborators, is now being used on a large scale in South

¹ 'Report of the International Conference of Representatives of the Health Services of certain African Territories and British India, Cape Town, November 15-25, 1932', *Quarterly Bulletin of the League of Nations Health Organisation*, vol. ii, no. 1, 1933, and 'Report of the Pan-African Health Conference, Johannesburg, November 20-30, 1935', *Quarterly Bulletin of the League of Nations Health Organisation*, vol. v, no. 1, 1936.

America, and less extensively in West Africa; also in England by C. M. Findlay for officials and others going out to West Africa. Three methods are in use; that originally used by W. A. Sawyer, S. F. Kitchen, and W. Lloyd with modifications by A. Pettit and G. J. Stefanopoulo, the attenuated mouse-brain vaccine of J. Laigret, and the tissue-culture virus vaccine. There is little question that successful vaccination gives great protection against the disease, but inexplicable symptoms of an alarming character have occasionally been produced.

(e) *Sleeping Sickness*

Tsetse-fly is widely distributed throughout Central Africa, infected areas being found in the West Coast, in the Belgian Congo, in East Africa, and as far south as the Rhodesias. New patches frequently occur, as migrations of fly are frequent in areas in which it is hitherto unknown. It must also be realized that the spread of the disease must in many cases be associated with the opening of new communications and the development of trading facilities. This factor may be in some measure reduced by the increasing substitution of the motor car for portage,¹ but there is still a wide field for the diffusion of infection through the movement of natives along routes which have not come under protective schemes.

The same family of blood-sucking flies conveys both human and animal disease, and not only occasions widespread human suffering, but makes it impossible to keep cattle and other stock in large areas. Thus in Northern Rhodesia and Tanganyika approximately half the total area of the territories is unsuitable for domestic stock; there is a very considerable infected area in Southern Rhodesia; and in the Gold Coast Colony, Ashanti, and the Southern Provinces of Nigeria the main reason why there are no animals for transport, for manure, for meat supplies or for milk, is the prevalence of tsetse-fly and the disease which they convey.²

It has been mentioned that as a result of an epidemic of sleeping sickness which broke out along the shores of Lake Victoria Nyanza

¹ See Chap. XI, p. 629, and Chap. XXIII, p. 1538.

² Address by the Rt. Hon. W. Ormsby-Gore: *Report of the Second International Conference on Sleeping-Sickness, Paris, November 5th-7th, 1929*, pp. 14-19 (League of Nations Health Organisation, 1928). See also Chap. XIII, p. 932.

in the early years of this century, and which is believed to have caused the death of over a quarter of a million people, the Royal Society sent two commissions¹ to Uganda to inquire into the disease. Sir Aldo Castellani, of the first commission, detected a trypanosome in the cerebrospinal fluid, and Sir David Bruce, of the second commission, first concluded that the disease was due to infection with a trypanosome. Professor F. K. Kleine, in 1909, discovered that the trypanosomes underwent cyclical development in tsetse. Stephens and Fantham differentiated between *Trypanosoma gambiense* and *T. rhodesiense* in 1910, and in the following year A. Kinghorn and W. Yorke showed the cyclical development of *T. rhodesiense* in *Glossina morsitans*. These researches, together with the League of Nations International Commission on Human Trypanosomiasis of 1926² under Dr. H. L. Duke, have laid the foundations for a rational outlook on the disease and its control, and have stated the problems which still require solution. Broadly, it may be said that the facts now generally accepted are that human trypanosomiasis, or sleeping sickness, is due to the infection of man with either of two species of trypanosome, *T. gambiense* or *T. rhodesiense*: that these trypanosomes are conveyed by certain species of tsetse-fly (usually *G. palpalis* in the case of *T. gambiense*, and *G. morsitans* or *G. swynnertoni* in the case of *T. rhodesiense*), either by mechanical transmission, that is, the direct transmission of a trypanosome from one infected person to another, or by cyclical transmission, after the trypanosome has undergone a certain part of its cycle of development in the tissues of the tsetse-fly. The latter is the more usual method, the former is probably a rare occurrence. *T. rhodesiense* causes a more acute disease for man than *T. gambiense*, and one theory of the development of human trypanosomiasis is that both parasites are altered forms of *T. brucei*, the cattle and game trypanosome, which normally dies when introduced into man, but which, so the theory postulates, can become pathogenic to humans when resistance is low, and once it has established itself can be passed from man to man by cyclical transmission in the tsetse fly. Holders of this theory believe that *T. gambiense*

¹ Royal Society: *Reports of the Sleeping-Sickness Commission*, 1903-8, 1910-14, 1915.

² *Interim Report of the International Commission on Human Trypanosomiasis*, 1927; *Final Report*, 1928.

is *T. brucei* which has been greatly modified by long-continued passage from man to man by cyclical transmission through the tsetse-fly. *T. rhodesiense*, on the other hand, is a more recent parasite of man, and it has been thought that even to-day new strains of *T. rhodesiense* are being developed from *T. brucei* of game. There can now be very little doubt that wild animals are a reservoir for *T. rhodesiense*. Although *T. rhodesiense* has been shown to survive in transmissible form in bushbuck for two and a half years, it is open to doubt whether the complete destruction of game of every description, in order to eliminate every possible vector, is in practice feasible. The object of the steps taken in Southern Rhodesia for the killing of game is mainly to limit the range of infection, and prevent access to an area of European settlement.¹

G. palpalis has entirely different habitats from *G. morsitans* and *G. swynnertoni*. The former lives in riverine bush for the most part, while the latter is a dweller in savannah country. Control measures are, therefore, not the same, though the object of both is to break the contact between the tsetse fly and man. The first attempt at control was made at the time of the great epidemic, when the whole Uganda population of the islands and shores of Lake Victoria Nyanza was evacuated to a safe distance from the tsetse-infested area. The measure was successful, and the tsetse fly which still infested the ravaged area eventually lost the trypanosome infection. To-day reoccupation of some of the islands and lake shore is taking place, so that man and tsetse fly are again in close contact, but as the introduction of a case of trypanosomiasis might be sufficient to begin another epidemic strict control of reoccupation is maintained. Elsewhere the fight against *T. gambiense* is directed to the breaking of contact; thus, tsetse-free watering and washing places are provided on infested rivers, and the need for the people to visit tsetse-haunted bush for firewood and building poles is lessened by planting eucalyptus or other quick-growing trees near villages, and by the introduction of clay bricks as a standard material of house construction. Extensive clearings of bush along tsetse-infested rivers have facilitated the isolation of blocks of infested bush from which the fly can be eliminated by trapping and hand-catching. This method has been carried out with success

¹ See Chap. XIII, p. 932.

in Kenya and on a smaller scale in Uganda. In Tanganyika Territory experiments have been carried out as to the best method of control of *T. rhodesiense*, a considerable organization, developed under the charge of the late Mr. C. F. M. Swynnerton,¹ having been maintained for some years at Shinyanga for this purpose by the Tanganyika government, with the assistance of a grant from the Colonial Development Fund.² In some districts the customary yearly burning of grass and bush has been controlled so that a large area should be burnt at one time, and the fly destroyed. Extensive clearing of bush has also taken place, while in other parts dense tree-barriers have been planted to prevent, or at least hinder, the movement of fly. These methods are reported to have been successful. In order that land cleared of bush should remain free of fly, scattered populations have been concentrated in the middle of reclaimed areas, and encouraged to cultivate in a centrifugal direction so as gradually to occupy extensive tracts of country.³

In the British East African territories, the attempt to deal with sleeping sickness may be said to have followed a double course, combining an attack on the habitat of the fly with the treatment of infected persons. It will be realized that the former line of attack is not limited to attempts to reduce the range of fly responsible for human trypanosomiasis, but extends also to measures designed to protect domestic animals. It involves a comprehensive study, on the entomological side, of the habits of the fly, and on the botanical side, of its vegetal habitat; it uses a great variety of methods, many of which require the co-operation of Africans, since they involve not merely the use of large bodies of labour, but occasionally the transfer of considerable native populations. In this work Tanganyika, and some other territories, rely largely on the assistance of the native administrations. In Uganda some use has also been made of the Sleeping Sickness Ordinance and Rules.⁴

It is perhaps the difficulty involved in these operations, and some uncertainty as to their efficacy, which has decided other

¹ C. F. M. Swynnerton, 'Tsetse Flies of East Africa', *Transactions of the Royal Entomological Society*, vol. lxxxiv, 1936.

² See Chap. XXIV, p. 1624.

³ See *Report to the League of Nations on Tanganyika Territory*, 1937, pp. 18-21.

⁴ *Laws*, cap. 46, vol. iii, p. 167.

administrations to confine control to the treatment of infected persons, aiming by this means to secure a progressive expansion of trypanosome-free areas. This is, in the main, the system followed by the French, who found the Cameroons affected by an epidemic which seems to have begun just before the War; in 1926 they instituted a permanent sleeping-sickness mission, for medical treatment of the disease, and this is the method which is now normally adopted in the territory.¹ It is also, in the main, the method followed in the Congo, reinforced by rules restricting movement to and from infected areas. The early attempts to clear the bush could not be pursued owing to the nature of the country, and the administration resorted to purely medical treatment, using first atoxyl and afterwards tryparsamide. As will subsequently be seen, the method used by both the French and Belgians involves an attack on the seriously affected areas by mobile medical sections, and the taking of legal powers to restrict the movement of infected persons and to secure their receipt of the full course of prescribed treatment. The recent introduction of the Bayer 205 group of drugs has raised some hopes that trypanosomiasis might be eliminated, for if all infected persons were so treated as to cease to be infective for the tsetse fly, the disease must cease to be propagated. The detection of all cases is, however, impossible in African conditions, save by the use of an extreme measure of control.

An important contribution to the control of trypanosomiasis has recently been made by Dr. H. L. Duke, who has shown that an intravenous injection of Bayer 205 protects the individual from infection with trypanosomiasis for at least three months. This method of prophylaxis has been used in Uganda to protect prospecting parties in sleeping-sickness areas. The medical authorities in Tanganyika are opposed to it, for fear of replacing obvious infections with inapparent infections which might fail to be diagnosed until too late for cure. In the French and Belgian territories where sleeping sickness is present, treatment with Bayer 205 is used on a large scale by the *équipes de prospection et traitement*.² Nigeria is at present faced with the problem of dealing with a very widespread distribution of the disease, which in places

¹ *Bulletin de l'agence générale des colonies*, Oct.-Nov. 1926, p. 1317.

² See below, p. 1174.

has assumed epidemic form. A grant from the Colonial Development Fund has been made to finance a scheme of control by extension of the present method of inspection and treatment, under a plan which resembles that of the French and Belgian territorial organizations. Temporary field dispensaries have been set up in infected areas in the Northern Provinces at which inoculations are given. Attendance at these centres is voluntary, but the Nigerian Sleeping Sickness Ordinance,¹ applied to the Northern Provinces of both Nigeria and the Cameroons under British Mandate, makes provision for compulsory treatment if necessary, also the proclamation of areas in which restrictions on movement of persons and stock may be imposed. In the Togoland under British Mandate, where there is no compulsion, it is considered doubtful whether really satisfactory results can be achieved without resort to it.

(f) *Plague*

Bubonic plague is carried by fleas and is normally a disease of rats, and human plague occurs only when the infected fleas attack human beings; for instance, heavy mortality in rats may compel the fleas to feed on other hosts. Whereas in Equatorial Africa the house rat is the common carrier, in South Africa field rodents such as the striped mouse, the multimammate mouse, and the gerbille are mainly responsible. The fullest recent description of plague in South Africa is by Professor Ricardo Jorge.²

Rodents undergo periodic fluctuations in numbers, the population increasing to such a degree that there is a food shortage and weakening of resistance followed by disease. It seems probable that the South African field rodents normally fluctuate in numbers, like the voles and lemmings of the northern hemisphere, and are reduced in numbers every few years by diseases harmless to man;³ it now seems, however, that bubonic plague has so spread among them that it has to some extent replaced these natural diseases. Preventive measures in African conditions usually consist of the disinfection of huts in infected areas by cyano-gas, which kills the rats; sometimes, however, the older methods of burning huts or of remov-

¹ Ordinance 1 of 1937.

² 'La peste africaine', *Bulletin de l'office international d'hygiène publique*, vol. xxvii, 1930; supplement to no. 9.

³ E. B. Worthington, *op. cit.*, 1928, chap. xvi.

ing the roof and re-thatching and re-plastering are used. Cyano-gas has the advantages of leaving the hut intact and killing other parasites, whereas the destruction of huts discourages Africans from reporting cases. These measures are perhaps of more value in calling attention to the danger from rat-infested huts than in preventing the spread of disease, and it is clear that little progress can be made until the contact with rats is broken by improved conditions of housing and hygiene.

The possibility that the incidence of plague, in parts of Africa other than the south, may depend on fluctuations in numbers of rodents and their fleas has been considered likely in connexion with the outbreaks in East and West Africa.¹ The recent history of the disease in Uganda, where there was a rise in incidence in 1936, lends support to the theory.²

All the East African territories have reported at intervals outbreaks of the disease with sporadic cases in the intervening periods. A small endemic area of plague in the Belgian Congo at the south end of Lake Albert has been studied for some years, and there seems no sign that it is spreading or decreasing in extent.³ Endemic centres occur elsewhere in East Africa, notably in Tanganyika.⁴

In Angola the first outbreak of plague was in 1921 in Loanda, to which the disease was probably introduced from Lisbon. The epidemic rapidly reached a climax and then steadily decreased, perhaps as a result of the widespread burning of huts to destroy rats. Since 1932 the South African plague carried by rodents reached Angola, but there have been few cases, and desert conditions which are unfavourable to rodents may prevent its spread. Minor outbreaks have occurred in Portuguese Guinea, the Ivory Coast, the Gold Coast, and Southern Nigeria, where, however, there has been no case since 1933. The infection of Senegal from Dakar has been more severe, but the height of the epidemic was reached in 1924 and it has since died down to small proportions.

Causes of the spread of plague need more extended investiga-

⁴ *Annual Medical and Sanitary Report*, 1931, pp. 7, 8.

tion: there is evidence¹ to show that the fleas infesting rats vary in number and species in town and country, and in stone and mud houses. Research is being carried out by Dr. Davis of the Wellcome Bureau at the Sir Alfred Lewis Jones Laboratory at Freetown, with a grant from the Royal Society of Medicine. Research on anti-plague inoculation has been carried out by Dr. E. P. G. de Smidt at the Medical Research Laboratory, Nairobi, and by Dr. J. H. Harvey Pirie at the South African Institute for Medical Research. Vaccines containing attenuated live plague bacilli have been advocated, but their use in Africa has not met with the same general acceptance as in India.

At the Pan-African Health Conference held in Johannesburg in 1935 the delegates agreed that methods of plague control cannot be standardized, especially in the case of rural areas, where circumstances must determine whether the attack should be against house or field rodents, or both, and whether it should involve vaccination of humans or not.

(g) *Relapsing Fever*

The characteristic symptom of the disease is high fever at regular intervals of about a week. The type known as tick fever, found in East and West Africa, is transmitted by a tick (*Ornithodoros moubata*), which is found in native huts and camping sites. Endemic in certain areas, especially along trade routes, it has sometimes reached epidemic proportions. In Uganda, at one time, all non-immune persons in prison in Ankole District inevitably contracted the disease. Control is dependent on tick eradication, and consequently on improved conditions of housing and hygiene. It is a frequent cause of illness among travellers, who, while they may have acquired a degree of resistance to the parasites infecting their own homes, succumb easily to the attacks of ticks in such places as rest houses.

Another variety of relapsing fever is that of which the vector is the body louse. It was endemic in French Guinea in 1921, and seems to have spread across Africa to the Sudan. The case mortality-rate among Africans is about 18 per cent., compared

¹ C. B. Symes and G. H. E. Hopkins, 'Notes on Fleas of Rats and other Hosts', Kenya Medical Department, *Records of the Medical Research Laboratory* (no. 1), 1932.

with from 1 to 5 per cent. in Europe,¹ and its spread in Africa is said to have been facilitated by the adoption of clothes.

(h) *Typhus Fever*

Much research on typhus fever has been done by Dr. A. Pijper in Pretoria, and a detailed account of the position has been given by Dr. E. H. Cluver.² There are three distinct typhus-like diseases in the Union, which are transmitted by ticks, rat-fleas, and lice. Tick typhus occurs chiefly in the low-lying region of the Transvaal, but cases are known in Southern Rhodesia and at the Cape. Rat-flea typhus is found among rats over an extensive area, though it is relatively uncommon among human beings; unlike plague, typhus does not kill the rats and hence the fleas do not often overflow to man. Louse typhus is the commonest type. Its incidence did not come into prominence until about 1919; from then until 1923 reported cases averaged over 8,000 annually, and although milder in South Africa than in Europe it is known to have caused 34,986 cases among Africans during the period 1923-35, resulting in 4,665 deaths; among Europeans in the same time there have been 686 cases with 32 deaths. The endemic area embraces about one-half of the Union, including the Transkei, Ciskei, and the Orange Free State. It is said that the rat-flea virus immunizes against tick typhus, but not against louse typhus; on the other hand, tick virus does not immunize against rat-flea typhus, but louse typhus immunizes against rat-flea typhus.³

Evidence in Kenya⁴ and in Uganda,⁵ where an outbreak of louse typhus occurred in the Kigezi District among a people clothed in sheep or goat skins, suggests that typhus fever may be present in East Africa to a greater extent than is at present known. Two

cases of the tick typhus have been reported from Uganda, but the louse-borne disease is said to be dying out as a result of a disinfector introduced for village use. The louse-borne type may exist in the Belgian Congo, since it was possibly from this territory that the disease reached Uganda.

(i) *Tuberculosis*

It is probable that tuberculosis was not prevalent to any great extent among African tribes in earlier times, but modern conditions, such as industrialization and urban life, have facilitated its increase, and it is now widely distributed.¹ In Africa, as in Europe, the disease is associated with poverty and overcrowding. In view of the apparent low power of resistance of Africans and the high mortality among African sufferers, the prevention of tuberculosis is among the more important health problems which engage the attention of governments and of employers of labour.

Since Professor Calmette in 1912 initiated the testing of West African natives with tuberculin, considerable information has been acquired as to the extent of the disease.² In some areas, usually those of dense population and with opportunities for contact with outside races, the infection rate is almost as high as in Europe, namely 80 to 90 per cent. of the adult population; in other areas, usually those of scattered population, or remote from outside influence, the rate is much lower, but may be as high as 50 per cent. of the adult population.

The susceptibility to tuberculosis of the Senegalese troops in France during the War attracted much attention; few had been infected before leaving Africa, and under war-time conditions in a non-tropical country, the inhabitants of which were relatively heavily infected, they were easily attacked by tuberculous disease, which took a much more fatal course than the usual type occurring in adult Europeans.³ There is little doubt that survivors returned to Africa and spread the disease, but the fact that no important

centres of infection seem to have been set up in the rural areas appears to indicate that the environment was unfavourable to its general spread. This view was confirmed by Professor S. Lyle Cummins in his investigation of the problem of tuberculosis in native mine-workers.¹ He held that the sunshine, comparative leisure, and certain customs found in African villages, such as that of burning the hut of a deceased person, militate against the extensive spread of the disease; also as diseased natives usually die after a short illness the period during which they may spread infection is limited. The spread of the disease is encouraged by overcrowding, such as that said to be caused by a hut tax, and in many places lack of timber has forced the natives to abandon house burning.

Although tuberculosis is usually found in overcrowded urban areas,² there are also extensive thickly populated rural areas which have high and increasing infection and disease rates. In Tanganyika,³ infection and disease rates vary directly with population density, suggesting that the major factor in the spread of tuberculosis is opportunity for contact with diseased persons.

In the South African and Rhodesian mines most African labourers are said to improve in health during their term of work, but unusual conditions of labour are often held to cause active disease where previous infection exists, and though medical inspection may be adequate there must often be a period, before diagnosis and isolation take place, when infection is spread. The importance of a period of acclimatization for newly recruited labour is now generally recognized.⁴

It has been shown that Africans are more sensitive to tuberculosis than Europeans.⁵ Post-mortem examinations also show that the type of disease resembles the acute rather than the chronic fibrous type usually seen in white races. The protective

⁵ S. Lyle Cummins, *op. cit.*, pp. 7 ff., 13.

reaction of the African's tissues appears to be deficient,¹ but on the other hand, the fact that many Africans are infected and do not become diseased, points to a considerable factor of resistance. In the Belgian Congo medical officers of the *Foréami* consider that individual resistance is increasing, and that the rule that every native patient must be isolated in hospital is of considerable value.² It is almost certain, however, that the natives' resistance to tuberculosis would be increased if their diet and living conditions improved.

There are large numbers of tuberculous patients in the Asiatic and European communities in Africa. The Indians of Zanzibar are heavily infected,³ and the same is undoubtedly true of Asiatics on the mainland.

Although tuberculosis has been found in cattle in Uganda,⁴ the French Sudan, and Tanganyika, human tuberculosis of bovine origin is believed to be rare in Africa. As in Europe, the principal form of tuberculosis is that of the lungs, which is not usually due to the bovine type of bacillus.

(j) *Leprosy*

While tuberculosis may be called a recent disease in Africa, tending to increase under the pressure of modern economic conditions, the leprosy bacillus (*Mycobacterium leprae*) would appear to have been with Africans since time immemorial, and the disease is prevalent among tribes which are comparatively unaffected by European contacts. It has been described as a disease associated with poverty, which should disappear with improved standards of living.⁵ The northern belt of Central Africa, from Nigeria to Abyssinia, is perhaps the most affected portion of the globe.⁶ About half a million cases of leprosy are already known in Africa, and the actual number may possibly be not less than a million. Leprosy is believed to be propagated by repeated contagion, and

⁶ W. H. Hoffman, 'Leprosy and the Cultural Development of Africa', *Africa*, vol. v, no. 4, 1932, pp. 455-63.

its spread would thus be favoured by conditions of African life, in which families live crowded together in comparatively small huts; the infection of families by everyday contact is said to be frequent.

Research has shown that the majority of cases in early stages can be arrested and even cured; advanced cases, though they may be improved, are usually intractable. Chaulmoogra oil and its derivatives are the principal drugs; ethyl esters have been used, especially in South Africa, with beneficial results, and gold preparations are valuable in leprosy affections of the eyes. In the prevention of leprosy, it is agreed that improvement of hygiene is the essential factor, and cases in a settlement have been arrested spontaneously, without any treatment, as a result of better conditions of life and nutrition. The segregation of persons suffering from the disease is considered of importance, and there are examples in various parts of the world where the disease has been completely eradicated from endemic centres by this means; the difficulty, however, of this course lies in the fact that sufferers do not always show visible signs of the disease and frequently highly infectious cases are not detected.¹ The British Empire Leprosy Relief Association, whose funds are derived largely from private sources, assists in establishing and equipping centres for treatment in British territories, particularly in Nigeria and Uganda. The Association, as a general rule, deprecates compulsory segregation of lepers, but encourages voluntary segregation by means of propaganda and grants, and emphasizes the necessity of measures being taken to prevent the infection of children. A committee of the Association and Toc H was recently set up, and sufficient funds obtained to train and support for five years in Africa a number of volunteers; five of these, later increased to seven, have been working in Nigeria since 1935 in close association with the Medical Department.

Legislation regarding leprosy varies from territory to territory; in some cases infectious lepers are compelled to enter special settlements, in others it is considered that compulsory isolation would encourage the concealment of cases.

In South Africa there are five principal institutions for leprosy, containing a total in 1937 of 2,270 persons, of whom 98 were

¹ W. H. Hoffman, *op. cit.*

Europeans, 97 coloured, 6 Asiatic, and the rest Africans. In addition 4,176 certified cases remained in their own homes.¹ In Basutoland a leper station, started in 1914, has a population of 684. Southern Rhodesia has two government leprosy hospitals at N'gomahuru and Mtoko, and a leprosy section subsidized by government is attached to the Mnene Medical Mission. As far as possible the patients live a normal life on large estates; the number of inmates increased from 508 in 1929 to 1,315 in 1936. The work has been assisted by grants from the Relief Association.²

In Nigeria and the Gold Coast,³ where leprosy is said to be virulent and increasing, special government organizations are established and much work is being carried out by medical missions, assisted by grants from the central government, the native administrations, and the Relief Association. Joint surveys in certain areas by government and mission doctors have revealed an unexpectedly high incidence. The average population of the leper colonies rose from 4,767 in 1934 to 5,116 in 1935; in addition some 2,380 lepers received treatment at native administration dispensaries in 1935. In Sierra Leone a recent survey of cases showed a total of 3,675, representing about 1 per cent. of the population. In Nyasaland twelve clinics are administered by missions, and receive grants from government in proportion to the number of cases treated. In 1936, 659 in-patients were treated in hospitals and 1,250 out-patients. Settlements at Dar-es-Salaam, Moshi, and Mkalama are controlled by the Tanganyika Government, which also gives assistance to mission settlements. The number of segregated cases in 1936 was 3,400.⁴ In Uganda a survey carried out in 1930-1 found the incidence ranged from 0.05 per cent. of the population in the Entebbe District to 1.26 per cent. in the Lango District. There are, in Uganda, three old-established colonies run by missions, and a new colony for able-bodied lepers started in 1934 which has now been taken over by the native administration. At each centre patients are supported by maintenance grants for the first year until they have established farms

⁴ *Annual Medical and Sanitary Report, 1936, p.* 36.

and become self-supporting; uninfected children are segregated from their parents as early as possible.

In French West Africa and in Togoland under French Mandate, a prophylactic campaign against leprosy has been organized in conjunction with a central institute for leprosy established in 1933 at Bamako, with research laboratories and a village housing over 300 patients, mostly from the Sudan and Ivory Coast. The institute has made the notable discovery that certain plants growing in the Ivory Coast and the Cameroons yield extracts which have effects on leprosy similar to the products of chaulmoogra oil. In French Equatorial Africa there is a leprosy village at Fort Lamy, and twenty-seven leper colonies have been established in the Cameroons under French Mandate. In some areas of the Belgian Congo the disease is particularly common, especially in Uélé-Népoko in Stanleyville Province, where a survey,¹ made in 1930, found in some parts as much as 12 per cent. of the population infected, and stimulated the *Croix Rouge du Congo* to start a campaign with financial assistance from the *Foréami*, the *Institut de Médecine Tropicale*, and the *Ministère des Colonies*. Against 28,000 cases treated in 1935, 57,000 were treated in 1936, and it is believed that on an average there are about 50,000 cases in the territory. The system followed for treatment is one of voluntary segregation in agricultural colonies where patients, as far as possible, live normal lives in villages and grow their own food. In the province of Stanleyville, for example, 71 leper villages had a population of 7,914 in 1936, and one settlement at Bibanga in the Lusambo Province had 455 inmates. A laboratory at Pawa in the same province, opened in 1934, is attached to a leper village and conducts leprosy research.

(k) *Yaws and Venereal Diseases*

The history of venereal diseases in Africa is obscure, but it is clear that syphilis was prevalent in East Africa before the European occupation; in Uganda, for instance, early medical missions found venereal diseases well established, and the infection was at that time commonly attributed to the Arabs. The slave trade also

¹ A. Dubois, *La lèpre dans la région Wamba-Pawa (Uélé-Népoko)*, 1932.

contributed largely to their spread. In recent times the importance of these diseases has been accentuated by the grouping of large numbers of African men and women in urban and industrial areas, where they are removed from the restraints of tribal custom, and promiscuous intercourse, prostitution, and temporary 'marriages' with strangers are common. Again, the absence of large numbers of the male population from the villages in search of wages¹ has encouraged a lower standard of morality in the rural areas, and has facilitated the spread of venereal diseases. Ignorance of the true nature of these diseases and of the result of neglect is prevalent, and their treatment by native herbs and medicines, which effect a temporary improvement, makes Africans careless; women are particularly reluctant to present themselves for treatment. While it is not possible to form any estimate of the extent to which these diseases are prevalent, there is evidence of their existence in a very serious form in many areas. It has been mentioned that in 1908 it was said that in Uganda some 90 per cent. of the population had been at some time or another infected. This could have been only a conjecture, though the experience of the Church Missionary Society hospital at Mengo went to confirm the grave prevalence of the disease among the native women. The native government of Buganda at one time, indeed, attempted to make attendance at hospital compulsory, and in 1913 the Lukiko passed a law for this purpose. But the high incidence is not confined to Uganda; it has been calculated that the incidence of yaws and syphilis in East Africa is 60 per cent., and Northern Nigeria, the French Cameroons, as well as other western territories consistently report the wide spread of venereal diseases.

The necessity for action in towns and mine locations in this matter is now generally realized; clinics are provided in the more important centres, and treatment is given at a large number of mission and government hospitals. At the same time it would seem that there is a lack of accurate knowledge among medical authorities as to the distribution of the various diseases in this group. At present it is said to be difficult to distinguish between yaws and syphilis in African patients. In West Africa where, in general, gonorrhoea is more widespread in the southern territories

¹ See Chap. XI, pp. 699-709.

and syphilis and yaws in the northern, estimates of incidence range from 50 to 90 per cent. of the population. In Nigeria, where the population is estimated at about 20,000,000, cases actually treated in 1936 were:

	<i>Government hospitals and dispensaries</i>	<i>Native administration dispensaries.</i>
Yaws	110,588	83,342
Syphilis	18,432	32,671
Gonorrhoea	16,386	20,839

In 1936 the cases treated at government institutions in Tanganyika, where the population is about 5,000,000, were: syphilis, 23,484; yaws, 70,682; and gonorrhoea, 9,619. Compared with these the figures in Uganda, where the population is about 3,500,000, were: syphilis, 63,695; yaws, 62,240; and gonorrhoea, 14,101.

The symptoms of yaws are generally removed by a few injections. This fact is of much value to the medical worker in gaining the confidence of Africans, but it complicates the treatment of other diseases, since the hopes raised of similar results from injections for the quick cure of other complaints may lead to disappointment. Moreover, a cure is often assumed when obvious signs disappear. Hence for the venereal diseases, particularly gonorrhoea, which needs a long course of injections, treatment is seldom persisted in long enough to effect a complete cure.

At present there is no laboratory test to differentiate yaws and syphilis, since all known reactions for the two diseases are the same.¹ Doubt exists whether yaws can produce lesions of the brain and spinal cord as does syphilis.² It has been suggested that yaws may confer immunity against syphilis, and hence it may be inadvisable to complete the cure for yaws if the patient may thereby become susceptible to syphilis.³ There is, however, no

¹ J. A. Carman, 'The Relationship of Yaws and Syphilis: are they two diseases or one?' *East African Medical Journal*, vol. ix, no. 5, 1935; G. Mattet, 'Syphilis et pian', *Bruxelles-Médical*, 1923, no. 46; T. F. Hewer, 'Some Observations on Yaws and Syphilis in the Southern Sudan', *Transactions of the Royal Society of Tropical Medicine and Hygiene*, vol. xxvii, 1934, p. 593.

² H. L. Gordon, 'Amentia in the East African', *Eugenics Review*, vol. xxv, 1934.

³ P. D. Connolly, 'Do Yaws and Syphilis confer Immunity against each other?', *Kenya and East African Medical Journal*, vol. vii, no. 12, 1931.

dispute that treatment which clears up cutaneous lesions leads to a reduction of incidence of the diseases in the next generation.

Perhaps the most systematic method of treatment has been adopted in parts of the French colonies. At Fort Lamy, for example, where the incidence of syphilis is put at 80 per cent. of the population, patients are given numbered metal discs which enable records to be consulted and facilitate the compilation of statistical data.

In the Belgian Congo the law obliges persons suffering from syphilis or yaws to present themselves at clinics at regular intervals so long as any sign of the infection remains.¹

(1) *Helminthic Diseases (parasitic worms)*

The importance of worm diseases in most African territories is now generally realized. In East Africa it has been established that over 90 per cent. of the population are infected with one or more kinds of worms, and frequently as many as six kinds have been found in the same individual.

Professor R. T. Leiper's department at the London School of Hygiene and Tropical Medicine has been prominent in revealing the life-histories and some of the pathological effects of worm infestation. Some species cause definite disease; for example, hook-worm (*ancylostomiasis*) produces a general anaemia and lowering of vitality; bilharzia (*schistosomiasis*) produces impairment of the functions of the liver and other organs, and, in serious cases, death from toxæmia; and certain tapeworms in the larval stage may be the cause of a kind of epilepsy. There can be no doubt that the general physical and mental activity of heavily infected persons is seriously affected.

The relation of these diseases to nutrition is important, and is still open to question. Certain parasitic worms appear to flourish in persons weakened by insufficient or unbalanced diet. On the other hand, heavy infestation in the African population may be a cause of malnutrition rather than an effect, and there are said to be several important worm infestations which are known to be uninfluenced by malnutrition. In certain cases feeding habits may cause infection, particularly in the case of peoples who eat

¹ See E. B. Worthington, *op. cit.*, chap. xvi.

raw meat and those who season their food with mineral salts collected from certain areas.

In Southern Rhodesia bilharzia is the most important helminthic disease. The incidence among the native population is believed to reach 50 per cent. in certain cases, and even for European children figures as high as 36 per cent. have been recorded. In the Union, propaganda and treatment campaigns have been organized by the Transvaal Bilharzia Committee in co-operation with School Medical Officers of the Education Department. In Northern Rhodesia it has been found that 31 per cent. of labour recruits for the Rhokana Corporation are infected with hookworm. Worm diseases are common in Nyasaland; in one village in Kuweraza District 100 per cent. of the people examined proved positive. That the drainage factor may play an important part in determining the incidence is suggested by the returns from mountainous and well-drained places, such as Mlanje and Zomba, which show 22·2 to 28·3 per cent. of hookworm infestation compared with 53 and 64 per cent. in Port Herald and Karonga, which are both low-lying and poorly drained. In Northern Nyasaland a heavy child mortality was traced to intestinal infection by worms resulting in cirrhosis of the liver. In Tanganyika Territory helminthic diseases account for 19 per cent. of diseases and 34 per cent. of deaths at government institutions. In Kenya, perhaps the most complete data on hookworm infestation recorded among a backward people were obtained in the Digo District in 1927-8. A selected village was subjected to detailed study at the end of the dry season, when infection should have been at its lowest, and it was found that every individual was infected, the average number of hookworm eggs being 466 per cubic centimetre of faeces.¹ Worm diseases are also very prevalent on the west coast, and it is said that in some areas infection by one or other form of helminthic disease is almost universal.

The remedial measures against these diseases, especially hookworm, depend largely on an improved standard of living, and on the maintenance of sanitary conditions. Difficulties in persuading Africans in rural areas to construct and use latrines are

¹ H. D. Tonking, 'Ancylostomiasis in Digo District', *East African Medical Journal*, vol. xi, no. 5, 1935.

well known to Administrative Officers, but much can be done if the native authorities are interested, and in this connexion the efforts now being made to train Africans as sanitary or health assistants are of importance.¹

(m) *Typhoid Fever*

Typhoid and paratyphoid infections are prevalent in most parts of Africa. It is commonly said that Africans do not suffer from them to the same extent as Europeans, but authorities in the Belgian Congo have noticed severe epidemics of typhoid among the natives of that territory. Diagnosis is by no means satisfactory on account of irregular symptoms, and the incidence is said to be higher than is generally supposed. Inoculation against these diseases has reduced much of the risk to Europeans.

(n) *Silicosis*

Silicosis, miners' phthisis, or 'rock drill fever' as it is sometimes called, is an occupational disease prevalent among miners in the Union of South Africa and in Southern Rhodesia: it has been defined as 'a more or less generalized fibrotic state of the lungs due to the inhalation of hard, flinty particles'.² The disease is chronic and generally progressive, but, although not infectious, it often leads to tuberculosis. Both European miners and native labourers are liable to the disease, but Europeans exhibit a higher incidence of simple silicosis, while natives, owing to their greater susceptibility to tuberculosis, show a rate of silicosis combined with tuberculosis which, in spite of their shorter period of service underground, is more than twice that of European miners. Silicosis has been recognized as a serious problem in South African mines for about forty years, and in the last twenty-five years much research has been carried out,³ as a result of which it has been possible to distinguish between 'simple' or uncomplicated

¹ See below, p. 1182.

² A. Balfour and H. H. Scott, *op. cit.*, p. 287.

³ See, for example, *The Prevention of Silicosis on the Mines of the Witwatersrand, being Report on the Investigations of the Miners' Phthisis Prevention Committee*, 1937; F. W. Simson, A. S. Strachan, and L. G. Irvine, *Silicosis in South Africa*, reprinted from *Proceedings of Transvaal Mine Medical Officers' Association (Special Supplement)*, 1930; A. Mavrogordato, *Contributions to the Study of Miners' Phthisis*, Publications of South African Institute for Medical Research, 1926, no. xix; *General Report of Miners' Phthisis Committee*, 1916, Appendix no. 6.

silicosis and silicosis accompanied by tuberculosis (the true miners' phthisis) or other infections.¹

In the Union of South Africa, from 1902 onwards, various commissions inquired into the causes of the disease and the provisions made for compensation, and in 1911 legislation was introduced providing for compensation to miners of both races.² Act 35 of 1925 consolidated previous legislation regarding both preventive measures and compensation, and the administration of the law is now vested in the Miners' Phthisis Board, and the Miners' Phthisis Medical Bureau under the Ministry of Mines. From 1919 to 1937 mining companies contributed a sum of £18,712,098 to the Board, and in 1935-6 the Miners' Phthisis Compensation Fund had a revenue of £1,053,258 and expenditure of £768,144 (the employers' contribution being £800,000). From May 1911 to March 1937 an aggregate amount of £16,803,828 was paid out to miners and mine inspectors; in the period August 1912 to March 1937, £1,130,309 was paid to native labourers, and £59,984 during 1936-7.³

Active measures to combat the disease aim at securing miners of good physique, at early detection of the disease, and at providing generally improved working conditions. A high standard of physical fitness is secured by means of an examination of all mine recruits before engagement; further examinations are held at six-monthly intervals, and miners in whom the disease is found are required to cease work underground. Africans are also subject to examination on termination of their contracts; the task is of considerable magnitude, as in 1934-5, for example, there were 255,816 African employees, of whom 198,193 were in underground service, and about 90 per cent. of the labourers are replaced annually. In 1934-5 the prevalence rate per 1,000 of simple silicosis among native labourers in the Union was 1.22; of tuberculosis with silicosis 0.75, and of tuberculosis alone 2.48; it compares favourably with the rates of 1925-6 which were respectively 1.13, 2.45, and 3.16.⁴ As many of the African miners in both the Union

¹ *Report of the Miners' Phthisis Medical Bureau for the three years ended 31 July, 1935*, U.G. 46, 1936, pp. 11 ff.

² Act 34 of 1911.

³ *Report of the Miners' Phthisis Board, 1 April, 1936-31 March, 1937*, U.G. 49, 1937.

⁴ *Report of the Miners' Phthisis Medical Bureau, etc.*, op. cit., U.G. 46, 1936, p. 55.

and Southern Rhodesia come from other territories and return home after the expiry of their contract, there is a serious risk that infected persons may spread tuberculosis in their home villages. The incidence rate among Europeans was 1.92 per cent. in 1920-3, 1.94 per cent. in 1927-8, and fell to 0.88 in 1934-5: general liability has diminished by 64 per cent.¹ Among both races there has been a decline in the liability to contract the disease, but apparently it is still liable to show itself after lengthy periods of service. Cases continue to occur among the miners of picked physique, and it seems as if medical preventive measures had done their utmost, and that further research must be directed towards the improvement of working conditions so as to exclude the harmful silicosis dust. It has been stated that progress has been made in this direction.² An International Conference on Silicosis was held at Johannesburg in 1930.

Miners' phthisis has also been a serious question in Southern Rhodesia for many years, though the position appears to be improving. During 1935-6 an inquiry was held into the incidence of silicosis and pulmonary tuberculosis among mine employees; as a result some improvements have been made, principally in early diagnosis, and in the provision of free X-ray facilities.³ A further inquiry was recently undertaken, but the report is not available.

It seems that the disease has not been detected among the natives working in the Northern Rhodesian copper mines. Elsewhere it is found on the Gold Coast, and an investigation into the incidence of silico-tuberculosis is to be carried out in connexion with the deep-mining area at Tarkwa.

(o) *Other Diseases*

In addition to the diseases discussed above, many others play a large part in the morbidity and mortality of African natives. Pneumonia is a frequent cause of death, and is especially prevalent where there is a strong contrast in the seasons, and among Africans who are exposed to unaccustomed conditions of labour, such as in the mines. In one district in Northern Rhodesia lobar pneumonia in the elderly and broncho-pneumonia in

¹ *Report of the Miners' Phthisis Medical Bureau for the three years ended 31 July, 1935*, U.G. 46, 1936, p. 2.

² *The Times*, Dec. 24, 1936.

³ *Report of the Public Health*, 1936, C.S.R. 23, 1937, p. 28.

the young are said to be the most frequent causes of mortality. Smallpox is present, to a varying degree, in different territories; vaccination is being more largely employed and should eventually control the disease. Measles, which has probably been introduced recently, sometimes produces serious symptoms among the African population. Epidemics in South Africa and the mining areas of Rhodesia have caused alarm in recent years. Dysentery, both amoebic and bacterial, remains the cause of considerable morbidity. Malignant diseases exist, but no conclusions can yet be drawn from the number of cases treated, as, with the growth of native confidence in European surgery, it is probable that hospital returns may show an apparent increase. The study of malignancy in the tropics has been advanced in a series of publications by the pathologists of Nigeria,¹ and elsewhere.

The question of the treatment of mental disorders among Africans is receiving increasing attention. Until recently, in many areas where other facilities were lacking, it was customary to confine difficult cases in the ordinary jails,² or put them in charge of relatives. A certain number of mental institutions have now been opened, such as the Mathari Mental Hospital at Nairobi, the institution at Ingutsheni in Southern Rhodesia, the mental hospitals at Dodoma and Intendi in Tanganyika, and the Colonial Asylum at Accra, which housed in 1936 as many as 445 cases. In Uganda a mental hospital was opened in 1936, but in some other territories the provision remains inadequate or does not exist: thus in Nigeria the visit of an expert alienist is awaited before any change is made in the present position. Some inquiry, but on a limited scale, has been made into the question whether any change in the incidence of mental disorder among Africans can be traced to the impact of European civilization. The investigations made on this subject at the Mathari Mental Hospital in Kenya, sometimes quoted in discussion on the 'backwardness' of Africans,³ were on too small a scale to be conclusive.

¹ E. C. Smith and B. G. T. Elmes, 'Malignant Disease in Natives of Nigeria: an analysis of five hundred tumours', *Annals of Tropical Medicine and Parasitology*, vol. xxviii, no. 4, 1934.

² See Chap. VII, p. 313.

³ See Chap. II, p. 36; also see Kenya, *Medical Department Annual Report, 1935* (pp. 5, 8-9), for a more detailed discussion of the possible effects of new social strains on the incidence of mental diseases.

One of the major problems confronting those engaged in health work in Africa is the lack of information as to the real incidence and extent of disease among natives. The population figures are frequently unreliable,¹ and the returns published in departmental and other reports, of cases treated in hospitals, dispensaries, mission stations, or by mobile units, bear little or no relation to the total amount of ill health which is suspected to exist, the extent of which is based on estimates only. Serious outbreaks of epidemic and infectious disease are obvious, but much fuller information is needed on general health before any conclusions can be arrived at as to the incidence of disease or as to the extent to which it is being checked or controlled by state and other health services. Valuable work has been done by intensive surveys in restricted areas, some of which have been noted, and the policy pursued in the Belgian Congo of conducting intensive campaigns in defined areas would seem to promise tangible results, both in the compilation of accurate information and controlling ill health; an extension of this method in other areas might well be undertaken. The recent report² on Northern Rhodesia stresses the need for accurate surveys in that territory especially, but the need is urgent throughout Africa; the present efficiency of services and plans for future development alike require a basis of reliable information.

III. INTERNATIONAL ORGANIZATION OF HEALTH WORK

International work in health and medicine has been organized since 1907, when the *Office International d'Hygiène Publique* was established. It has a permanent committee, representing fifty-three governments and including delegates from a number of African territories, and a permanent secretariat in Paris. Its activities cover a wide field, but are concerned primarily with the prevention of particular infectious diseases by international sanitary conventions. The recent International Convention for the Sanitary Control of Aerial Navigation has special reference to Africa.

The Health Section of the League of Nations consists of a

¹ See Chap. IV, pp. 104 ff., and E. B. Worthington, *op. cit.*, chap. xvii. Also W. M. Macmillan, *op. cit.*, p. 41.

² *Report of the Commission on the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, pp. 293 ff.

General Advisory Health Council which has the same membership as the committee of the *Office International d'Hygiène Publique*, a Standing Health Committee, and the Health Section of the League Secretariat. The work carried out under its auspices on such subjects as sleeping sickness, malaria, tuberculosis, leprosy, and public health services has been of great value to Africa. The Permanent Commission on Biological Standardization, also appointed by the Health Organization of the League of Nations, held a conference at Geneva in 1935 and had as its main objects the spread of knowledge regarding international standards and the establishment of national centres for this purpose. It influenced the formation of a new Biological Control Laboratory in Capetown for work on the standardization of vaccines and sera. Dr. M. D. Mackenzie, of the League Health Organisation, undertook two missions to Liberia¹ and Dr. Anigstein² has carried out a survey of the people. The results of activities of this nature are published in the *Quarterly Bulletin of the Health Organisation*, and the three-monthly *Epidemiological Reports* and the weekly *Epidemiological Record* include statistics and data from many countries.

The International Conference of Representatives of the Health Services of African Territories and British India, held at Capetown in November 1932, under the auspices of the League of Nations and the *Office International*, was attended by representatives of all the principal British territories, and of Angola and Moçambique. The Pan-African Health Conference, held at Johannesburg in November 1935, included representatives of the French and Belgian colonies; the subjects discussed at these conferences included the training of native medical subordinate personnel, the transmission of disease by aircraft, measures against plague, and research in animal diseases.³

The International Health Division of the Rockefeller Foundation has been connected with Africa chiefly through its work on yellow fever, to which reference has been made above.⁴

³ *Quarterly Bulletin of the Health Organisation of the League of Nations*, vol. ii, no. 1, 1933; vol. v, no. 1, 1936.

⁴ See above, p. 1127.

The Epidemic Intelligence Bureau at Singapore, established after a conference at Singapore in 1925, held under the auspices of the League of Nations, receives telegraphic reports regarding epidemic diseases from a number of countries, including the East Coast territories of Africa and the Union, and transmits a weekly summary to all countries concerned.

The International Missionary Council, with headquarters in London, is composed of representatives of a large number of Protestant missionary societies, and in view of the number of hospitals and health centres supported by missions, it must be included in a survey of international organizations assisting in improving health in Africa. There is also in London a British Advisory Board on Medical Missions.

IV. ORGANIZATION OF HEALTH SERVICES IN BRITISH TERRITORIES IN AFRICA

(a) *Union of South Africa*

In the Union, a separate government department, the Ministry of Public Health, was established in 1919, and medical and health work is under the general control of the Secretary for Public Health of the central government.¹ Private practice is fully developed and the hospitals depend to a large extent on part-time work by practitioners and specialists. The provision of hospital facilities is mainly the responsibility of the provincial governments, which afford very considerable financial assistance. For certain purposes, such as the control of sanitation and outbreaks of infectious diseases, most municipalities have health officers and health departments, but the scope of these organizations varies so much in the absence of uniform legislation that it cannot be summarized. In most districts medical officers, mostly part-time, known as District Surgeons, are employed by government for the treatment of indigent persons; in June 1937 these numbered 363, of whom 340 were part-time. The Rand mines employ a large number of doctors and have their own hospitals and dispensaries.

¹ *The Official Year Book of the Union of South Africa*, 1934-5, gives a full account of medical facilities: and earlier issues contain a summary of the history and development of the health administration.

A Committee of Inquiry,¹ recently appointed by the Minister of Public Health, recommended that, as regards the European population, compulsory health insurance should be instituted in urban areas, and that the number of District Surgeons in rural areas should be increased, using where possible the services of doctors residing locally; while in the native areas, where medical services are inadequate for the needs of the population, a general extension is recommended, including a larger staff of doctors, an African nursing service, and a system of health visitors. There are in the Union 544 hospitals (including private nursing homes, maternity homes, and mine and factory hospitals), of which 260 are for Europeans only and 122 for non-Europeans only. They include 9,413 beds for Europeans and 15,372 for non-Europeans, but it is noteworthy that more than half the hospitals for natives, and nearly half the beds, are maintained by the mines and factories. The patients treated in 1937 were 172,555 Europeans and 326,128 natives, but of the latter 198,177 were treated in mine and factory hospitals. There is, in proportion to the non-European population, a relative lack of hospital accommodation for natives, other than those for whom the mines and factories provide; and the system under which 340 of the District Surgeons out of a total of 363 are part-time only, inevitably means that natives in the reserves, and indeed in many other areas, are dependent on attendance at the hospitals for medical facilities.

Besides devoting attention to the problems of silicosis and tuberculosis, the South African Institute for Medical Research at Johannesburg is carrying out investigations in connexion with plague, pneumonia, meningitis, and other bacterial diseases, and it has a field research station at Eshowe in Zululand for the study of malaria. The expenditure on the Institute for the year 1935-6 was £70,013, contributed partly by the government and partly by the gold-mining companies. The University of Witwatersrand Medical School also conducts research, in close association with the Institute.

The Research Grant Board of the Union, instituted in 1918, advises the government on medical and other research and

¹ *Report of the Departmental Committee of Inquiry: National Health Insurance*, U.G. 41, 1936, pp. 71-2.

administers all government grants-in-aid. The South African Association of Private Laboratories was recently inaugurated to promote co-operation and has encouraged such valuable research work as that on typhus.

(b) South-West Africa

In South-West Africa the medical service is controlled by the Medical Officer of the administration, stationed at Windhoek, and there are one whole-time and fourteen part-time District Surgeons appointed on the same basis as in the Union. There are five state-aided hospitals for Europeans, three Roman Catholic mission hospitals for Europeans and natives; the Rhenish, Anglican, and Finnish missions also maintain hospitals and medical stations. Otherwise, medical services for Africans appear to be restricted to three state-owned native hospitals with a total of 103 beds. In 1936, government institutions treated 926 European and 1,686 non-European in-patients, and 203 European and 5,631 non-European out-patients. Public health expenditure amounted to £23,831 out of a total ordinary expenditure of £731,802.

(c) Basutoland

In Basutoland medical work began in 1844 as a result of French missionary activity, but until Dr. E. C. Long was appointed Principal Medical Officer in 1894 there was little advance. The medical system in 1936 included eight government hospitals with twelve European and 148 native beds, giving a figure of one hospital bed for every 4,000 of the coloured and native population. The staff consists of a Principal Medical Officer, ten Medical Officers stationed in out-districts and one as relief, one District Surgeon and the medical superintendent of the leper settlement; there are also fourteen European staff nurses and five matrons. The African staff included in 1936 an assistant medical officer, ten dispensers, one qualified nurse, and thirty-eight unqualified nurses and attendants. The health service in rural areas is poorly developed, as the existing staff is only sufficient to deal with hospital work. In 1936 in-patients of all races numbered 3,298 and attendances at government dispensaries 82,952. Expenditure amounted to £48,932 out of a total ordinary expenditure of £294,883.

(d) Bechuanaland

In Bechuanaland the staff in 1936 included a Principal Medical Officer stationed at Mafeking and eight other government doctors; there were also four subsidized mission doctors and one other subsidized doctor. The hospital system consisted of three government hospitals at Lobatsi, Serowe, and Francistown, each with some four beds for Europeans and twenty for natives, four smaller mission native hospitals, and one more hospital for natives which is in course of erection (1937). The service appears to be insufficient even for curative work, especially in the west and north of the territory where practically no medical assistance exists, and there is a need for dispensaries and for trained native nurses and native subordinate staff.¹ A sanitary inspector has been appointed for work in village conditions as a first step to preventive work. In 1937 two travelling dispensary units, each consisting of two lorries, a Medical Officer, and African dispensers, were provided to tour outlying districts.² In 1936 the hospitals admitted 1,751 in-patients and there was a total of 70,933 attendances (27,196 being first attendances) at government and medical-mission hospitals and out-stations. Government expenditure was £20,126 out of a total ordinary expenditure of £167,310 in the year ending March 1937.

(e) Swaziland

In Swaziland there was little medical work before 1926, when the Nazarene Mission established a hospital at Bremersdorp and the Wesleyan Mission started a hospital at Mahamba. A government hospital was established at M'Babane in 1931, and there are now four government hospitals, two for Europeans and two for Africans, with 20 beds for Europeans and 125 for Africans. The European staff consists of two mission doctors and four government doctors. The provision is still inadequate for natives, especially in the rural areas, which are served by a few small dispensaries. It has been suggested that it would be more practical to enlarge the scope of the mission work by government grants rather

¹ *Report of the Commission on the Financial and Economic Position of the Bechuanaland Protectorate*, Cmd. 4368, 1933, pp. 72-7.

² *Official Year Book of the Union of South Africa*, 1937, p. 1250.

than to expand the government establishment.¹ The last return from Swaziland gave 2,416 in-patients and 30,591 out-patients; expenditure was £14,892 out of a total of £131,537.

(f) *Southern Rhodesia*

In Southern Rhodesia medical and health services have, since 1923, been controlled by the Public Health Department. Private practice has become well established and many private doctors aid in the work of the hospitals. There are well-equipped hospitals with accommodation for Europeans and other races at Salisbury and Bulawayo and smaller hospitals in eight other towns. Africans are further provided for by six small hospitals and two government institutions for the accommodation and treatment of lepers. The larger mining companies maintain special hospitals for their employees. There are, however, about 800,000 natives living in reserves or on unalienated Crown land where there is only a limited number of medical missions subsidized by the government.² To meet this situation progress has been made in the last few years in the establishment of a network of medical dispensaries throughout the native reserves. The aim is eventually to have a series of small base hospitals, each surrounded by a ring of dispensaries; the dispensaries are staffed by trained native orderlies, where possible under the administrative supervision of the local Native Commissioner, and are in most cases served by the local government Medical Officers. In many areas missions co-operate and maintain clinics.

The government laboratory at Salisbury is the chief centre of research, and, among other studies, work on the anaemias as they exhibit themselves in the European and in the native inhabitants of the country has been carried out. The Bulawayo Bacteriological Institute, established in 1930 and subsidized by government, became, in 1936, an entirely government institution with the name of the Public Health Laboratory, Bulawayo; its work has hitherto consisted mainly of routine examinations.³ In 1937 government hospitals provided 580 beds for European and 1,111 for Asiatic

¹ *Report of the Commission on the Financial and Economic Position of Swaziland*, Cmd. 4114, 1932, pp. 54-8.

² *Report of the Public Health*, 1935, C.S.R. 14, 1936, p. 11.

³ *Report of the Public Health*, 1936, C.S.R. 23, 1937, p. 42.

and African patients, and treated 8,040 European and 13,704 Asiatic and African in-patients; out-patients were 22,685 and 44,521 respectively. The staff included 46 Medical Officers and 271 nurses, and 506 African assistants. Departmental expenditure was £252,573 out of a total government expenditure of £3,456,704.

(g) *British Colonial Dependencies*

The Secretary of State is advised by the Chief Medical Adviser and by the Colonial Advisory Medical Committee,¹ which examines the annual medical reports from the colonies and maintains contact with similar advisory committees on education, agriculture, and animal health, in order to correlate policy. In 1934 the medical services of all the dependencies were unified into the Colonial Medical Service, a change which has rendered the transfer of officers from one dependency to another easier and more frequent.² The medical staff at the Colonial Office consists of a Chief Medical Adviser and an Assistant.

The London School of Hygiene and Tropical Medicine is a training-ground for colonial workers, and a centre of research in entomology, protozoology, and helminthology, as well as in clinical medicine, while the recent incorporation of the Ross Institute has created a section for the investigation of practical methods of dealing with tropical health problems.

The Bureau of Hygiene and Tropical Diseases is maintained by the Colonial Office at the London School of Hygiene and Tropical Medicine, and has as its principal function the collection of information regarding hygiene and tropical diseases. It publishes information and abstracts of important technical papers in several languages in two monthly periodicals, the *Tropical Diseases Bulletin* and the *Bulletin of Hygiene*. From 1931 onwards a Supplement to the *Tropical Diseases Bulletin* has been published, consisting of summaries of the medical and sanitary reports from British territories. The Imperial Agricultural Bureau publishes a group of journals covering practically all the sciences touching agriculture; those on entomology and nutrition also cover medical entomology and

¹ See Chap. VI, p. 161.

² *Dominions Office and Colonial Office List*, 1936, p. 596.

human nutrition, and are of considerable importance in connexion with Africa. The Bureau of Nutrition, at the Rowett Institute, Aberdeen, abstracts the literature on nutritional subjects. The Nutrition Committee of the Economic Advisory Committee was set up to study and advise on the problem of nutrition.¹

The Liverpool School of Tropical Medicine is an important headquarters of training and research, especially in relation to the West African colonies. The School has sent expeditions to Africa, and maintains the Sir Alfred Jones Laboratory at Freetown.² The Director, who is also consulting pathologist to the Government of Sierra Leone, is assisted by two or more experts. The staff has undertaken a survey of diseases and parasites in West Africa.

The Medical Research Council, maintained by government, supports a malarial research unit at the London School of Hygiene and Tropical Medicine for the study of anti-malarial drugs; it finances work of a similar nature at the Molteno Institute at Cambridge. It has created two research fellowships on tuberculosis in Eastern Africa; and has instituted an inquiry into the nutritional problems of Nigeria. The Council intend to establish permanent posts for research in tropical medicine,³ the holders of which will work partly in the tropics and partly in British institutions to which they will be attached. The first stage has been the creation of tropical research fellowships, of which two junior and two senior have already been awarded. The Tropical Medical Research Committee, an advisory body including representatives of the Medical Research Council, the Colonial Office, and the Liverpool and London Schools of Tropical Medicine, has been formed in connexion with the extension of research in the tropics, and has issued publications in 1928, 1929, and 1935 on the state and progress of medical research in the colonies, dependencies, and mandated territories.

In general it may be said that since the reorganization of the Colonial Medical Service in 1934 each British territory has had a

¹ See Chap. XXIV, p. 1618, and E. B. Worthington, *op. cit.*, chap. xvii.

² See above, p. 1136.

³ *Report of the Medical Research Council, 1936-7*, Cmd. 5671, 1938, p. 159.

Medical Department controlled by a Director who is usually assisted by a deputy director and, where the work justifies it, by an assistant director. In the larger towns sanitation is in the charge of a Medical Officer of Health who may or may not be a government official. Certain dependencies still divide their medical staff into a health division and a medical division, but others have abolished this distinction.¹

In the East African territories the Conference of East African Governors² assists in maintaining touch between workers in medical as in other subjects. Conferences on the co-ordination of general medical research were held at Entebbe in November 1933 and at Nairobi in 1936, and two on tsetse flies and trypanosomiasis at Entebbe in 1933 and 1936. In West Africa inter-territorial conferences have not yet become a feature of medical activity, though a conference on yellow fever was held at Dakar in 1928, with representatives from the British West African colonies as well as from French territories. Local branches of the British Medical Association held conferences at Nairobi in 1932, at Dar-es-Salaam in 1934, and at Kampala in 1936.

Most territories have laboratories staffed by pathologists and other specialists, who are largely concerned with routine work but are sometimes able to undertake original research in addition. The most important of these centres are at Lagos, Accra, Free-town, Nairobi, Kampala, Dar-es-Salaam, and the Yellow Fever Research Institute at Entebbe in Uganda³ (until recently the Human Trypanosomiasis Institute).

The dissemination of information regarding work done in other territories, and new methods and discoveries, is a problem of importance to scientists working in African conditions. The Bureau of Hygiene and Tropical Medicine and also the *East* and *West African Medical Journals* assist in this direction, but it is felt in some quarters that local advisory bureaux on a small scale are also necessary. In Kenya an honorary Library Committee, under the auspices of the British Medical Association, has undertaken the study of literature and the circulation of information.⁴

¹ See below, p. 1196.

² See Chap. VI, p. 182.

³ *Annual Report of the Medical Department*, 1936, p. 8.

⁴ *East African Medical Journal*, vol. xi, no. 10, 1935.

(h) Northern Rhodesia

In Northern Rhodesia difficulties in extending medical services are accentuated by the large area of the territory and the low density of population, amounting only to 4.7 a square mile, and it is clear that the provision made in regard to the health conditions of natives is inadequate.¹ It is stated that over half the territory remains unprovided with medical facilities.² By comparison with other dependencies the proportion of the total revenue devoted to this work is small. Medical Officers have large areas to supervise, and the claims of non-native practice and lack of easy communications prevent frequent visits to rural districts and dispensaries; there seems also a lack of means for ascertaining the facts about the health conditions in the native reserves. The government maintains seven European hospitals, twelve native hospitals, and eighteen rural dispensaries. The dispensaries are staffed by Africans, many of whom are stated to be imperfectly trained. The staff includes ninety-three African orderlies and seven microscopists.

With the help of a grant of about £20,000 from the Colonial Development Fund, plans have been made for the erection of a hospital and training school at Lusaka, two other hospitals, and twenty-two dispensaries.³

In addition to the government service the Roan Antelope, the Mufulira, and the Rhokana Copper Mining Companies maintain fully staffed hospitals for European and native employees. Missions are also active and together support twenty-seven hospitals and dispensaries, five of which are controlled by qualified medical practitioners and the rest by trained nurses or by other partially trained staff. The government gave a subsidy of £3,050 in 1936 to medical-mission work.

The hospitals provide 132 beds for Europeans (figures for natives not available), and in 1936 1,691 European and 10,700 African in-patients were treated, and 52,151 African out-patients; the rural dispensaries admitted 1,534 Africans and treated 24,160 out-patients. Government expenditure in 1936 was £852,417 (total)

¹ *Medical Report on Health and Sanitary Conditions*, 1936, p. 1.

² *Report of the Commission on the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, p. 290.

³ *Ibid.*, pp. 292-3.

ORGANIZATION IN BRITISH TERRITORIES IN AFRICA 1163
and £65,091 (medical). Staff provided for 1938 includes 20 European Medical Officers, 39 European nurses, and 3 sanitary inspectors.

(i) *Nyasaland*

Nyasaland, by contrast with Northern Rhodesia, has a relatively small area and denser population, concentrated especially in the southern part, and medical services can be more easily organized. The staff is relatively larger, and a number of Asiatic sub-assistant surgeons supplement the work of the Medical Officers. The African staff of over 200 includes 16 hospital assistants, 177 dispensers, 19 sanitary inspectors, 40 vaccinators, &c. There are 16 European Medical Officers, 2 sanitary inspectors, 11 nurses, and 9 sub-assistant surgeons. Eighteen medical posts designed to have a European Medical Officer in charge are at present filled by Asiatic sub-assistant surgeons or even by African hospital assistants, and in the northern areas in particular many rural districts are out of reach of dispensaries. There were 2 European hospitals, 15 native hospitals, and 93 rural dispensaries in 1936. There is also a number of mission hospitals and dispensaries; the Scottish missions have from early days been conspicuous in medical work. In 1936 it was stated that there were 26 African and 1 European mission hospitals; the qualified staff, which, however, varies from year to year, included 11 doctors and 22 nurses. The bed accommodation varies from under 10 to 129 in the various hospitals and dispensaries. A laboratory at Zomba is in charge of a government pathologist, but routine duties prevent much time being given to research. In 1931 a grant of £43,079 was made to the territory by the Colonial Development Fund for public health, most of which has been spent on hospital buildings. The Medical Department is represented on a Native Welfare Committee, established in 1935, to facilitate co-operation between the social services. As in other East African territories the Education Department includes the teaching of hygiene in its curriculum; the Jeanes School¹ has special courses for chiefs, which are said to have had some influence on hut-building and on the choice of suitable village sites.

¹ See Chap. XVIII, p. 1228.

The following information is available for 1936: in-patients—165 Europeans, 9,757 Africans and others: out-patients—1,685 Europeans and 435,489 Africans and others. In rural dispensaries 301,738 cases were treated. Total government expenditure was £617,573 and medical £48,181.

(j) *Tanganyika Territory*

In Tanganyika Territory the Medical Department is arranged in administrative, medical, health, and laboratory sections, with a special section for dealing with the medical side of sleeping-sickness work. The organization at Shinyanga, previously referred to,¹ is not a part of the health organization. It is occupied with research into the habit of the tsetse, and with experiments in methods of control; it is maintained largely by a grant from the Colonial Development Fund, which in 1938 contributed a grant of £207,974, to be spread over a period of seven years, for tsetse control work. There are also maintained, at the expense of the Colonial Development Fund, three research units which are devoted to trypanosomiasis research in a laboratory at Tinde, to malarial survey, and to tuberculosis research. The Asiatic staff of 55 assistant and sub-assistant surgeons and 24 compounders is an important part of the establishment; the African subordinate staff includes 109 dispensers, 40 sanitary inspectors, vaccinators, hospital orderlies, and nurses. In 1936 there were on the European staff 50 Medical Officers, 30 nurses, and 21 sanitary inspectors. There are 9 hospitals for Europeans. The native hospital system consists of 48 government general hospitals, 2 mental hospitals, 297 tribal and 37 Medical Department dispensaries.² The missionary societies maintain a number of hospitals for natives with, in 1936, a staff of about 18 qualified doctors. Their work is often of a high quality and includes maternity work and the training of African orderlies and nurses. The tribal dispensaries are maintained by the native authorities, and £18,565 was spent from native treasuries in 1936 on medical services, and 529,954 cases were treated.³ In 1936 government hospitals provided 73 beds for Europeans, 118 for Asiatics, and 2,012 for Africans; European in-patients were 1,609,

¹ See above, p. 1132.

² *Annual Medical and Sanitary Report*, 1936, pp. 19–20.

³ See below, p. 1189.

and Asiatic and African 36,412; European out-patients were 3,108 and Asiatic and African 594,908. Total government expenditure was £2,029,824, and Medical Department £185,737.

(*k*) *Kenya*

In Kenya the Medical Department, developed after 1905, is arranged in administrative, medical, sanitary, and laboratory divisions. There are proportionately more European Medical Officers, nurses, and health visitors, but fewer Asiatic qualified men than in Tanganyika Territory. The Medical Research Laboratory at Nairobi, which was completed in 1931, also provides some service for the neighbouring colonies. Besides carrying out research on the more usual problems it has made interesting investigations into the physiology of Africans, their brain structure, mental conditions, blood morphology, and chemistry.¹ Provision for Europeans is made by three principal hospitals at Nairobi, Mombasa, and Kisumu, and smaller hospitals in townships, as well as a number of private nursing homes which have grown with private medical practice. For Asiatics and Africans there are 6 hospitals in the towns, some 23 in native reserves, and 6 small hospitals in the northern parts of the colony, including Turkhana, the Northern Frontier Province, and Lamu. There are a number of mission hospitals in the territory, and in 1936 a grant of £3,700, made by the government, was apportioned between the Methodist Missionary Society, the Church of Scotland Mission, the Church Missionary Society, the Seventh-Day Adventists, and the Neukirchen Mission Society. The Medical Department has taken a large share in projects for the improvement of living conditions in the native reserves; through its agency efforts have been made to improve the type of native house and the village sanitation, and importance is attached to the provision of sanitary inspectors, who are general advisers on native betterment under the Medical Officers. The policy of the Department is to set up in each large native district a 'health centre'—an organization consisting of a hospital with a Medical Officer and European nursing sister, and a number of out-dispensaries; there is also posted to each district a European sanitary inspector, among whose duties is the

¹ See Chap. II, p. 37.

instruction of the natives in hygiene and in the building of houses.¹ A certain number of out-dispensaries, staffed by Africans, are established in the native reserves, seven of which are maintained by the local native councils.

In 1936 government hospital statistics were as follows: beds—European 73, Asiatic 52, African 1,928. European in-patients were 1,817, and Asiatic and African 46,632; European out-patients were 3,609, and Asiatic and African 408,788; out-dispensary first attendances were 640,261. The European staff included 54 Medical Officers, 50 nurses, 3 health visitors, and 12 sanitary inspectors; there were 26 Asiatic sub-assistant surgeons (2 being assistant surgeons); the African assistant staff of 1,204 included 33 hospital and 92 laboratory assistants, 30 health workers, and 648 dressers. The Medical Department's expenditure was £197,049, and total government expenditure £3,350,381.

(1) *Uganda*

In Uganda the Medical Department is subdivided into administrative, executive, and laboratory divisions. A distinctive feature of medical work in the protectorate is the employment of a number of qualified African assistants, whose presence has enabled the European Medical Officer to devote more time to his preventive duties, and to the general superintendence of the medical and health work of his district. The Asiatic staff has been reduced, owing to the increase in trained Africans, and now consists of 12 sub-assistant surgeons and several nurses. Among the African staff are 30 medical assistants, trained at the Mulago Medical School, holding appointments in the African Civil Service,² who have in some cases replaced Asiatic sub-assistant surgeons and are, where practicable, in charge of small districts. The medical laboratory carries out routine duties, and a medical entomologist attached to the entomological section of the Mulago agricultural laboratory deals with problems of entomology. Research has been carried out at the Human Trypanosomiasis Institute at Entebbe, which now houses the Rockefeller Foundation team investigating yellow fever in East Africa. There is a mental hospital at Mulago, four general hospitals for Europeans, nine for Asiatics, and twenty-three for Africans.

¹ *Medical Department Annual Report*, 1936, pp. 54 ff.

² See Chap. VI, p. 234.

A policy of establishing dispensaries in rural areas is actively pursued, and in 1936 these numbered ninety-three, and attendances of out-patients amounted to over three millions. The cost of erecting them is usually met from native administration treasuries; recurrent charges are borne by the native treasuries or by the central government, either wholly or in part, according to the ability of such native administrations to pay. In 1936 expenditure on medical and health services from native treasuries amounted to £19,283. Rural dispensaries are developed as village institutions at which the necessity of submitting to sanitary measures and general medical knowledge are taught. Health work in rural areas has effected improvement in safeguarding water supplies, drainage of swamps, sanitation of native dwellings, and the introduction of an improved type of house which it is within the financial capacity of the African to build. Associated with the dispensaries are itinerant medical orderlies who hold out-patient clinics at fixed places. Medical missions have been especially active in Uganda; the work of Sir Albert and Lady Cook, of the Church Missionary Society, is indeed outstanding; the hospital built by them at Mengo trains African nurses and midwives,¹ and the twenty-four maternity and child-welfare centres attached to the mission deal with some 150,000 cases annually. Similar training schools and maternity centres in Uganda are organized by the Franciscan Sisters.

Government hospital bed accommodation was: European 34, Asiatic 56, African 1,273. In-patients were: European 517, Asiatic 1,345, African 29,215; out-patients: European 3,076, Asiatic 7,566, African 368,151. The European staff included 45 Medical Officers, 35 nurses, and 17 sanitary inspectors. There were, in addition to the 30 trained African assistants, 34 health workers and a large and varying number of other employees. Departmental expenditure for 1938 was estimated at £190,121 and total government expenditure at about £2,179,659.

(m) *Nigeria, and the Cameroons under British Mandate*

The medical and health organization in Nigeria and the British Cameroons is divided into medical, health, laboratory, and sleeping-

¹ See below, p. 1190.

sickness services. It is noteworthy that the medical staff now includes 14 African Medical Officers, qualified in Europe and holding appointments similar to those of Europeans, and a number of medical assistants are now in training at Yaba.¹ Other subordinate African staff includes dispensers, nurses, midwives, sanitary inspectors, and vaccinators. The laboratory service is centred at the African Hospital, Lagos, and the Research Laboratories at Yaba, which include the former Rockefeller Yellow Fever Laboratory.² There are subsidiary centres at several of the principal hospitals in the Northern and Southern Provinces.

The hospital system includes twelve European hospitals. The African hospitals in 1936 numbered twenty-four in the Northern Provinces, of which thirteen are under the native administrations; and thirty-three in the Southern Provinces, of which six are wholly and three partly under the native administrations. Some of the hospitals maintained by the native administrations, for example that at Kano, are large and well equipped institutions. In addition there is an extensive system of native administration dispensaries, of which some 300 were established by 1936, 121 in the Northern and 179 in the Southern Provinces.

Many of the missions, particularly in the Southern Provinces, have important medical centres; in 1936 they controlled twenty-two hospitals for Africans, ninety-seven dispensaries, sixteen leper settlements, and 116 maternity and infant-welfare centres, and treated some 216,500 patients.

It has already been mentioned that Nigeria, in order to deal with its sleeping-sickness problem, is now undertaking a combined scheme of inspection and treatment by means of a territorial organization similar to those working in French and Belgian territories.³

The government hospitals provide 148 beds for Europeans and 3,503 for Asiatics and Africans. There were 1,116 European in-patients, and 60,098 others; out-patients were: 7,176 European and 650,209 Asiatic and African. The European staff includes 114 Medical Officers, 62 nurses, and 37 sanitary inspectors: the African staff has also 5 junior medical officers, 26 assistants, 11

¹ See Chap. VI, p. 235; also, below, p. 1184.

² See above, p. 1127.

³ See above, p. 1134.

health visitors, and a large subordinate personnel. Government expenditure on medical and health services amounted to £387,600 out of a total expenditure of £6,061,348.

(n) *The Gold Coast, and Togoland under British Mandate*

In the Gold Coast and British Togoland the Medical Department is centred at Accra and has medical, health, and laboratory branches. The European staff is relatively large considering the size and population of the territory. The medical branch includes eight African Medical Officers, qualified in Europe, and an African dentist on the senior staff. The laboratory branch at Accra is mainly engaged in routine duties in connexion with hospital work. There are six European hospitals, apart from the infectious diseases hospital at Accra. The Gold Coast hospital, erected at a cost of over £254,000, has a permanent staff of five Medical Officers. It is a training centre for nurses, dispensers, and other subordinates, and receives cases needing special diagnostic methods or treatment from other hospitals. There are thirty-two African general hospitals, each in charge of a Medical Officer, nine hospitals for contagious diseases, sixteen village dispensaries, and two field hospitals in the extreme north of the territory, dealing mainly with sleeping sickness. There are also child-welfare centres, three of which are financed by the Gold Coast Branch of the Red Cross. While many hospital buildings have been erected in the important towns, at considerable expense, dispensaries in rural areas are as yet few, and it appears that the initiative is left largely to the local native authorities, who, in the absence of a regular 'native treasury' system,¹ have no means of making the necessary provision for them. Although road communications in the Colony and Ashanti enable patients to reach hospitals with comparative ease, a further extension of rural dispensaries is necessary to reach the bulk of the population. Some of the missions maintain welfare centres and hospitals.

Government hospitals provide 68 beds for Europeans, 995 for Africans in the general hospitals and 121 in the contagious diseases hospitals; in 1936 there were 931 European and 26,150 African in-patients, and 2,095 European and 282,035 African out-patients. The European staff includes 54 Medical Officers, including

¹ See Chap. IX, p. 474.

3 pathologists, 1 alienist, and 2 specialists, 32 nurses, 21 sanitary inspectors, and 3 health visitors (1 government and 2 Red Cross Society); the African assistant staff of 512 includes 236 nurses, 113 sanitary inspectors, 105 dispensers, village overseers, and laboratory attendants; there are also 7 African health visitors. Government medical expenditure in 1936 was £312,413 (recurrent) out of a total government expenditure of £2,337,357 (recurrent).

(o) *Sierra Leone*

In Sierra Leone there are separate medical and health branches of the Medical Department. In addition to the European staff there are 7 qualified African doctors, including a senior Medical Officer, a pathologist, and a considerable subordinate staff of nurses, dispensers, &c. There is a central European hospital at Freetown. The Connaught Hospital for Africans at Freetown dealt with 2,549 in-patients and 18,193 out-patients in 1936, and there were in 1936 four other smaller African hospitals. Three mission hospitals in the Protectorate and one in the Colony are subsidized by government, and a dispensary system has eight centres in the Colony and fourteen in the Protectorate.

In 1936 government hospitals provided 14 beds for Europeans and 535 for Africans; there were 180 European and 5,270 African in-patients and 474 European and 110,524 African out-patients. The European staff included 15 Medical Officers, 7 nurses and 3 sanitary superintendents; the African subordinate staff of about 160 included dispensers, nurses, health visitors, and sanitary inspectors. Government (medical and sanitary) expenditure for 1936 was £66,910.

(p) *The Gambia*

The Medical Department and most of the staff are concentrated at the Victoria Hospital at Bathurst. The health conditions of the capital are far from satisfactory. A reclamation scheme to improve the level of a part of the town which is submerged in the rainy season has been postponed, and the existing conditions of bad drainage are aggravated by bad housing. It is held that the dangers of plague infection are great and will continue to be so until rat-proof buildings replace the present hovels and drainage

is improved. Malarial infection is prevalent; there are also important problems of sewage disposal in Bathurst and the riverine towns. A senior research worker has been sent to the colony with a scholarship from the Medical Research Council. The Protectorate area, containing the greater part of the population, has long been starved of medical care. A new hospital is, however, to replace an inadequate institution at Georgetown. A small bush hospital has been erected at Bwiam, where sleeping sickness is prevalent; it treated nearly 1,000 sufferers from sleeping sickness in 1936. A dispensary at Kaiaf, also opened in 1936, treated 3,000 cases of various diseases in a few months, and the immediate success of these institutions proves the urgent need for medical treatment in rural areas. A child-welfare centre has been started near Bathurst, and a leper camp, recently constructed by a progressive chief, had a sudden influx of sufferers from the French territories and elsewhere, attracted by free housing and food.

Throughout the territory in 1923 there were 10,381 out-patients (first attendance) and 676 in-patients; in 1936 these amounted to 45,223 and 1,893 respectively and included 2,000 cases of sleeping sickness, 4,046 cases of yaws, and about 500 cases of leprosy. There appears to have been an undue concentration of medical work in the capital and the colony surrounding it. In 1937 there were three government hospitals, the Victoria, Georgetown, and Bwiam, providing 9 beds for Europeans and 98 for Asiatics and Africans; in-patients numbered 49 Europeans, 25 Asiatics, and 1,619 Africans; out-patients, 115 Europeans, 61 Asiatics, and 31,576 Africans. The European staff included 6 Medical Officers, 4 nurses, and 2 sanitary inspectors; there were 2 African assistants and about 40 others. Government medical expenditure was £32,110 and total expenditure £343,323.

V. ORGANIZATION OF MEDICAL SERVICES IN FRENCH TERRITORIES

A full account of the public health services in the French colonies as they were ten years ago was published in English by the League of Nations Health Organisation,¹ and also in statements prepared

¹ S. Abbattucci, 'Public Health Services in the French Colonies', *League of Nations Health Organisation*, 1926.

for the International Colonial Exhibition of 1931.¹ Medical policy has not changed materially since then. The following account affords some comparison with the organizations in British and Belgian colonies.

There is no central institute for research and training in France wholly comparable with the London School of Hygiene and Tropical Medicine,² but the Pasteur Institute in Paris serves similar functions as a centre to which government may refer for advice. The Institute has branches in the French dependencies at Dakar, Kindia, and Brazzaville, directed from Paris, but receiving a grant from the local governments; the institute at Dakar is one of considerable importance. An inspectorate³ of all the colonial health services has head-quarters at the *Ministère des Colonies* in Paris.

(a) *French West Africa*

The organization in French West Africa is typical of the French preference for centralized and clearly co-ordinated methods in administration. Each of the colonies in the federation has a *Chef du Service de Santé* directly responsible to the Governor; for this purpose the district of Dakar is regarded as a distinct colony. The *Chefs du Service de Santé* receive guidance in matters of policy from the Inspector-General of Health Services at Dakar,⁴ and address regular reports both to the Governor of the colony and to the Inspector-General at Dakar. In each colony the *Chef du Service de Santé* has a staff of European doctors of whom the majority are military and have undergone a course in tropical diseases at the *École d'Application* at Marseilles. In addition the trained African establishment includes 'auxiliary' doctors, midwives, and health visitors who have passed through the medical school at Dakar. These 'auxiliaries' are an important feature of the French system; the character of their training will be described elsewhere.⁵ The European staff in French West Africa includes 180 Medical Officers, 68 nurses and dispensers, and 30 health visitors; the African staff has 185 'auxiliary' doctors, 250 health visitors, and 1,733 subordinate personnel.

¹ *Le gouvernement général de l'A.O.F., Exposition coloniale internationale de 1931.*

² See above, p. 1159.

³ See Chap. VI, p. 189.

⁴ See Chap. VI, p. 239.

⁵ See below, p. 1185.

There has been and is still some difficulty in obtaining French civil doctors, and hence a number of foreigners have been engaged as assistants, and some military doctors are seconded to the civil branch. Each colony has its principal hospitals, of which those at Dakar, St. Louis, Bamako in the Sudan, and Abidjan in the Ivory Coast are regarded as first class. That at Dakar has 432 beds for Africans, principally surgical cases, and a very popular maternity centre for Africans which deals with some 800 deliveries a year. Dakar has also a unique feature in its medical centre, the *Poli-clinique*, run in conjunction with the medical school;¹ it is an out-patient centre for the African population, in which an average of more than a thousand consultations takes place every day. There are separate departments for infant welfare, maternity cases, and radiology, and every schoolchild in Dakar is examined by the staff twice a year. The hospital at Bamako, on the other hand, appears to be mainly for Europeans. Hospitals of the second category are at Conakry in Guinea, Porto Novo and Cotonou in Dahomey, while third-class hospitals, each with a surgeon and radiographer in addition to clinicians, are at Bobo-Dioulasso and Ouagadougou in the northern part of the Ivory Coast and at Niamey in the Niger Colony.

Staff not absorbed by these hospitals is distributed according to a plan which aims at providing each administrative *cercle* or district with at least one *centre médical* staffed by a European doctor assisted by African auxiliaries. These centres deal with urgent surgical cases and supervise subsidiary centres (*infirmeries*) each in charge of African 'auxiliary' doctors, who in their turn are responsible for dispensaries in charge of African *infirmiers* or nurses. In some parts of the Ivory Coast and Guinea there are, in each administrative *cercle*, up to nine medical posts with 'auxiliary' doctors, but more usually two or three. This system is almost complete in Dahomey and the lower regions of Senegal, and is being extended as native doctors and other staff are trained at Dakar, but there are large areas still without dispensaries. In principle the extension of work is dependent on the availability of European supervision, since the system does not contemplate leaving an African 'auxiliary' in independent charge. This policy

¹ See below, p. 1185.

may be contrasted with that followed in some British territories, such as Tanganyika and Nigeria, where only partially trained Africans are often left without European supervision for considerable periods. There is a further difference between French and British policies: the French hospitals are regarded largely as the headquarters of field stations, whence curative and preventive medicine is made available in rural areas, whereas those in British territories are intended mainly as centres for treatment. In the smaller French hospitals, patients are encouraged to live with their relatives, who provide them with food while they undergo treatment—a system which undoubtedly adds to the popularity of the hospital, as those missionary bodies who practise it have found. It has, however, been criticized in some quarters as lowering the standards of hygiene and orderliness aimed at in European hospital services. For sanitary work the French rely on the ordinary medical staff, except at Dakar and other large towns, where special police supervise the carrying out of anti-malarial work, and a separate sanitary service for the destruction of vermin is in operation.

Special organizations deal with certain diseases, particularly sleeping sickness.¹ These, known as *équipes de prospection et traitement*,² number at present ten in the northern part of the Ivory Coast, two on the western border of that colony, three in Dahomey, two in the Sudan, one in Senegal, and two in Guinea, and twelve others are in formation. Each *équipe* consists of a European doctor, one or two African auxiliary doctors, and a number of African *infirmiers*, some of whom are trained in microscopic work. The methods of the *équipe* are of some interest. The doctor in charge and the microscopists select a group of villages, examine the whole population, and note on a card, which is then handed to each patient, the diseases found; the African auxiliary doctor then establishes treatment centres, and patients suffering from sleeping sickness, and also other curable diseases, are treated until the disease is, as far as possible, eradicated. By this means it is proposed to clear up one area after another, and as each is vacated by the special *équipe* it is left for the ordinary system of *centres médicaux* and dispensaries to keep observation and to give any

¹ See above, p. 1133.

² See E. B. Worthington, *op. cit.*, chap. xv.

further treatment that may be required. The African personnel for this special sleeping-sickness work are trained at Ouagadougou on the Ivory Coast, where three Europeans, including a bacteriologist and an entomologist, are permanently resident.

The African branches of the Pasteur Institute are widely consulted by the colonial medical organization, and perform many routine functions such as the preparation of vaccines; the branch at Dakar, for example, provides yellow-fever vaccine¹ for all the territories. There is also a bacteriological laboratory at Bamako in the Sudan, with a staff consisting of a French doctor and five African *infirmiers*, which produces vaccines for rabies, smallpox, and tuberculosis. There are other similar laboratories for routine work at St. Louis and elsewhere under the control of the *Chefs du Service de Santé*. Medical reports are not published separately for each colony, but a general report, and accounts of scientific work by colonial doctors, appear each year in the *Annales de médecine et de pharmacie coloniale*, which is an official publication of the *Ministère des Colonies*. A central institute for leprosy has already been mentioned.² Serious cases are compulsorily segregated. In 1935 over 12,000 new cases were detected and treated, besides 13,000 old cases.

Although private organizations and missions do not play so important a part in French African medical work as they do in the Belgian Congo, their work has been extended considerably in recent years. Local branches of the *Croix Rouge Française* and of the *Berçeau Africain* are in direct contact with their headquarters in Paris, and are mostly concerned with infant welfare. The Catholic and Protestant missions are responsible for some dispensaries and leprosy hospitals in French West Africa. Recent information from French West Africa reports 11 government hospitals and 437 ambulances and dispensaries; beds available for patients are 788 (European) and 5,484 (African). In-patients were 4,731 Europeans and 42,785 Africans; out-patients were 19,859 Europeans and 3,113,819 Africans. Out of a total government expenditure of 615,000,000 francs, medical expenditure accounted for 38,000,000.

¹ The vaccine is made according to the Laigret method from the brains of white mice.

² See above, p. 1143.

(b) Cameroons under French Mandate

In the Cameroons under French Mandate the staff of the official *Service de Santé* included in 1936 45 European qualified doctors and some thirty European chemists, dispensers, and sanitary agents. The auxiliary African staff numbered 667. Good hospitals are established in each regional headquarters, with *centres médicaux*¹ in the district headquarters and dispensaries in charge of *infirmiers* in the subdivisions. There is one hospital for Europeans and four for Africans, three *centres médicaux* for Europeans and eighteen for Africans, and thirty-eight dispensaries, of which eleven are provided with beds. The total number of beds at these institutions is fifty-four for Europeans and 2,064 for natives. There are fifteen maternity centres and nineteen dispensaries for infant welfare, with a total together of 792 beds. Laboratory service is provided by the *Institut d'Hygiène* at Douala, and there are thirteen centres for contagious diseases, besides the leper colonies already mentioned.² Sleeping sickness, regarded as the most important disease in the territory, is dealt with by *équipes de prospection* with a special staff. Six *équipes* are permanently at work followed by twelve detachments for treatment. By a compulsory system of attendance and recording systems, a medical census has been made in much of the area. Furthermore, the movements of natives in all sleeping-sickness districts are controlled by a system of medical tickets. Medical missions are active and have a staff of 11 qualified doctors, a number of Europeans with medical diplomas, and a trained African staff of 174 *infirmiers*; 10 hospitals, two of which were under construction in 1936, and thirty-seven dispensaries with a total of 752 beds are maintained.

In 1936 hospital in-patients numbered 220 Europeans and 15,728 Africans; the dispensaries treated 9,601 in-patients and 134,316 out-patients, and the mobile units a total of 596,555. In 1935 the total government (ordinary) expenditure was 57,798,926 francs and that of the *Service de Santé* 8,978,269 francs.

(c) Togoland under French Mandate

In Togoland under French Mandate the medical staff included in 1936 13 Europeans, of whom 10 were qualified doctors, and

¹ See above, p. 1173.

² See above, p. 1143.

6 African auxiliary doctors trained at Dakar and 197 other African assistants. There are central European and native hospitals at Lomé, 5 *centres médicaux*, 21 dispensaries, and 5 maternity centres. Sleeping sickness was dealt with by one *équipe de prospection*, with 7 treatment detachments, and 15,000 new cases were detected in 1936. A special sanitary service has been established in Lomé to reduce the incidence of plague, rabies, malaria, and yellow fever. A laboratory has been attached to the Lomé hospital and is used for routine examinations only. Missions carry out a certain amount of medical work.

In 1936 there were 62 European and 4,255 native in-patients and 933 European and 544,515 native out-patients. Total government expenditure was 25,748,748 francs and that of the *services sanitaires* 3,863,897 francs.

(d) *French Equatorial Africa*

French Equatorial Africa has a similar medical organization to that in French West Africa, but on a smaller scale; there has been unusual difficulty here in maintaining the necessary cadre of Medical Officers. In 1936 the staff consisted of 80 doctors, 46 European nurses (*infirmiers*), chemists, midwives, and health workers, and some 650 African subordinate staff—nurses, dressers, and sanitary inspectors. There were in the same year 5 hospitals, 52 dispensaries, some of which were movable units, 46 health centres; 66,736 cases were treated in hospital, and some 2,750,000 consultations given. As in French West Africa, hospitals are regarded as the headquarters of outside work, but as yet there are no native auxiliary doctors and midwives, such as are trained at Dakar. *Équipes de prospection* for sleeping sickness function, though on a smaller scale than in French West Africa; field work of this kind and village treatment are difficult in view of the four months' rainy season. Sleeping-sickness villages are established by the *équipe* system for the treatment of serious cases, who are compulsorily segregated. There is a leper village at Fort Lamy. Medical missions are also active.¹ In 1936, 66,736 cases were admitted to

¹ See, for example, the works of A. Schweitzer: *On the Edge of the Primeval Forest*, 1922; *More from the Primeval Forest*, 1931.

hospital; 12,567 new cases of sleeping sickness were diagnosed in addition to 13,000 previous cases treated. Budgetary provision for the *Service de Santé* amounted to about 20,000,000 francs.¹

VI. ORGANIZATION OF MEDICAL SERVICES IN THE BELGIAN CONGO AND RUANDA-URUNDI

The *Institut de Médecine Tropicale Prince Léopold* at Antwerp collaborates with the state laboratories in the Congo, and the results of research are published for the most part in the *Bulletin de la Société Belge de Médecine Tropicale*. The State Medical Service of the Belgian Congo has its headquarters in Brussels at the *Ministère des Colonies*. There is a state laboratory at Léopoldville with a large research staff, and others at Coquilhatville, Stanleyville, and Élisabethville, each with one officer, discharging for the most part routine duties.

Although the government service is responsible for medical work in every district, there has been a greater development of unofficial organizations than in the British or French colonies. In a sense these are comparable to the preventive health services in Belgium which are largely in the hands of voluntary associations. They function in well-defined areas and are controlled by the state through legal agreements in the case of mining companies, and through conventions or in return for subsidies in the case of benevolent societies and missions.

The Belgians have concentrated to a marked degree on medical work in rural districts. The Congo is divided for administrative purposes into provinces and districts, and each district is subdivided into a number of territories. These are portioned out into the charge of the official organizations known as the *Service de l'Assistance Médicale aux Indigènes (Sami)* and the unofficial bodies known as the *Service Auxiliaire de l'Assistance Médicale aux Indigènes (Sadami)*. The *Sami* includes the state service, and a subsidiary organization specially endowed, the *Fondation Reine Élisabeth pour l'Assistance Médicale aux Indigènes (Foréami)*; while the *Sadami* includes the numerous medical missions and also two important organizations, the *Croix Rouge du Congo* and the *Fondation Médicale de l'Université de Louvain au Congo (Fomulac)*.

¹ *Annuaire de documentation coloniale comparée*, 1936, vol. ii, p. 218.

The *Foréami*, which started in 1930, has large financial resources and has accomplished a great deal of work. A capital sum of 150,000,000 francs was provided as a permanent endowment, 100,000,000 from the Congo Government, 50,000,000 from the Belgian Government, and an additional gift of 288,853 from Queen Elisabeth.¹ The annual expenditure has risen from 2,250,000 francs in 1931 to nearly 11,000,000 in 1934; some twenty-seven Belgian doctors and twenty sanitary agents, together with a large number of African assistants, are maintained permanently in the field. The government has given the *Foréami* complete charge of the medical work in a large zone, in which it has organized a more thorough medical service for Africans than in the rest of the colony. The private medical societies, especially the missions, assist and are paid subsidies. The policy is to concentrate on one area for a few years, to eradicate as far as possible preventable disease, build hospitals, dispensaries, doctors' houses, and roads, and then to hand the cleaned area over to the state service to maintain the work with a comparatively small staff. The *Foréami* then moves on to the next sector to continue the process. For the six years after the organization came into existence, the principal area of activity was in the Bas-Congo among the Bakongo tribe. The centre of attack has now been moved to the adjoining sector of Kwango, where the building of roads, houses, and dispensaries is well advanced. There is a secondary centre for campaigns against sleeping sickness in the Ruzizi-Tanganyika region where this disease is rife.²

The *Sadami* services are mainly in the hands of the *Missions Nationales*,³ mostly Roman Catholic, and receive government grants: they support eight doctors and a number of semi-qualified Europeans. Protestant missions, however, do considerable work and in 1934 they maintained 29 European doctors with a number of hospitals and dispensaries.

The *Croix Rouge* started in 1925 and is probably the first unofficial medical organization in Africa apart from missions. It aims at obtaining results in a limited area, and its main work has been concentrated in the Uélé district, where a staff of four

¹ *Foréami, Rapport Annuel, 1933*, p. 5.

² *Foréami, Rapports Annuels, 1931-3.*

³ Chap. XVIII, p. 1271.

doctors and eight sanitary agents is in charge of rural dispensaries, maternity work, and leper villages.¹ It has also established other centres organized by local committees; thus at Léopoldville, where the native town has a population of about 25,000 men and 10,000 women, venereal-disease clinics have been opened; at Coquilhatville a maternity centre has been started, and village dispensaries are being established in the neighbourhood of Élisabethville.

The *Fomulac*, like the *Cadulac*,² which is concerned with native agricultural improvement, originated from the colonial enthusiasm of the University of Louvain. Its objects and methods are similar to those of the *Croix Rouge*. Two important centres have been established, at Kisantu and Katana, and a smaller post at Yasa. Four doctors are maintained in Africa by the organization.

The mining and other companies, such as the *Union Minière du Haut-Katanga*, the *Société des Mines d'Or de Kilo-Moto*, the *Forminière* and the *Huilleries du Congo Belge*, maintain efficient medical services for their employees.³ In all some fifty doctors are supported in Africa by the companies. Concessions carry the condition that hospitals and schools have to be provided for the natives, but several of the companies have done far more in these directions than they were bound to do, and the influence of the companies' medical services has extended considerably beyond the immediate vicinity of their undertakings. Some account has already been given of the medical services maintained by the mines;⁴ it may be added that both Katanga and Kilomoto maintain a nutrition consultant; both companies avail themselves also of the services of mission medical centres, and in the region of the *Forminière* a child-welfare centre, the *Bergeau Kasai*, has been formed at Tshikapa. The *Huilleries du Congo Belge* support maternity hospitals and training schools for native midwives.

In 1936 the Government of the Belgian Congo maintained 25 European, 2 Asiatic, and 70 African hospitals, providing 317 beds for Europeans, 17 for Asiatics, and 6,420 for Africans: 2,913 European and 85,279 African in-patients were treated and 14,584 European and 836,322 African out-patients. The European

¹ See above, p. 1143.

³ See Chap. XI, p. 681.

² See Chap. XIII, p. 953.

⁴ Ibid., pp. 673-82.

staff included 174 doctors, 6 *médecins hygiénistes*, 16 *agents sanitaires*, and 243 nurses; the African staff included 1,920 assistants, nurses, &c., and 31 *gardes sanitaires*. The 1937 Budget provided 62,375,218 francs for the medical service out of a total of 665,487,207 francs.

In 1936 there were 4 hospitals in Ruanda-Urundi; there were 54 European and 4,720 African in-patients, with a further 1,679 admissions to other medical centres. A total of 995,894 Africans were treated by government and the subsidized mission medical services. Total government expenditure was 31,279,468 francs and that of the *Service d'Hygiène* 4,833,825 francs.

VII. ORGANIZATION OF MEDICAL SERVICES IN PORTUGUESE TERRITORIES

In Lisbon there is a School of Tropical Medicine forming a centre of research and training. In Moçambique a state medical service is directed by a bureau with head quarters at Lourenço Marques. In 1934 there were 13 hospitals and the staff included 75 doctors, 12 chemists, 110 European and 120 African assistants and nurses. The state service aims at providing a hospital with radiological and research departments in each district under a Medical Officer who will supervise dispensaries in sub-districts in charge of African assistants; but how far this policy has been carried out is not clear. A central laboratory is attached to the hospital at Lourenço Marques where investigations into sleeping sickness are carried out; there are hospitals also in 10 other urban centres and a mental institution for Africans at Marracuene. Medical work by missions, both Roman Catholic and Protestant, is stated to be important; the latter maintain 3 hospitals and 10 dispensaries. A Central Commission for Public Charity and Assistance, with head-quarters at the capital, has branches in the out-lying districts. It maintains the *Instituto João de Deus* at Lourenço Marques and the *Instituto Elias Garcia* at Moçambique for the care of children, and also undertakes maternity work and general welfare work.

In Angola there is said to have been an expansion of medical work after the First Congress of Tropical Medicine of West Africa was held at Loanda in 1923. In 1935 a state medical service provided 15 hospitals and employed 65 doctors and a number of

European assistants, and courses of training are held for African subordinate staff. Also in 1935 the Protestant missions had 9 hospitals and 89 dispensaries with 8 doctors and 21 European assistants. Medical work is also undertaken by the Roman Catholic missions, and in 1934 they had 6 hospitals and 42 dispensaries. There is little evidence that health work is being done in rural areas on a scale which may be compared with that of the French or Belgian Governments.

VIII. MEDICAL EDUCATION OF AFRICANS¹

The medical service, like other technical services in Africa, can be envisaged as a pyramid the base of which is formed by a large body of African subordinate staff, the apex by the fully qualified Medical Officers, and the central part by the African 'auxiliary' doctors or 'medical aids'. Apart from any other consideration, financial reasons make it impossible to contemplate that the extension of medical and health services should be attained by a proportionate increase in the number of fully qualified medical men. It has been shown² that in West Africa a number of African medical men, qualified in Europe, have been employed in superior service. But, viewed from the financial standpoint, their employment can only ensure the saving of that proportion of superior-service pay which is deemed to represent the extra emolument given to a European for serving overseas. Nor, on the other hand, can expansion be achieved by enlarging the purely subordinate staff, which has been described as the base of the triangle. Practical considerations fix in each service the ratio which must be observed between the supervising and the subordinate ranks, and in the case of the medical services it would clearly be dangerous to disturb this ratio. If experience elsewhere is any guide, expansion can best be achieved by enlargement of the 'intermediate' services³ which can, as their training progresses, take their own share in supervision.

There does not exist in Africa any institution designed to afford Africans an opportunity of gaining full medical qualifications in the sense in which that is understood in Great Britain or in countries

¹ See E. B. Worthington, *op. cit.*, chap. xv.

² See Chap. VI, p. 257.

³ See above, p. 1168.

with which the British General Medical Council has concluded agreements for the reciprocal recognition of qualifications. Something will be said elsewhere¹ of the difficulty encountered by African students in obtaining a medical degree at any of the universities in the Union. There are, in South Africa, a few African medical men in private practice; they have, however, obtained their qualifications in Great Britain. French policy excludes on principle the possibility that diploma-holders from a local institution, such as Dakar, should hold a charge of independent responsibility, and even senior members of the auxiliary medical service, who have successfully passed the equivalent of post-graduate courses, are only allowed to take up private practice if they obtain a special permit to do so. That the British territories do not at present contemplate making provision for Africans to take a full medical degree is largely due to the acknowledged lack of the necessary facilities for pre-vocational education. The success of a medical degree course depends as much on the existence of an adequately educated section of society from which to draw its recruits as it does on the quality of the vocational training given in the course itself.

The need for training an 'intermediate' class of medical auxiliaries was appreciated at an earlier date in French West Africa than in the British territories. The East African territories have in the past employed a number of Asiatic assistant and sub-assistant surgeons. A few of these had taken a medical degree at one of the Indian universities, but the majority had taken a diploma at a provincial medical school; the former degree was recognized, subject to some conditions, by the British General Medical Council; the diploma ranked roughly as equivalent to a 'licentiate'. West Africa did not avail itself of this supply, and it is still the practice for Europeans to perform a large amount of routine diagnosis and treatment. Africans are now being trained as medical assistants at the South African Native College in the Union, at Yaba in Nigeria, and at Mulago in Uganda. French West Africa has Dakar; the Belgians have lately opened a medical school at Léopoldville. It is proposed to give some details about each of these institutions.

In South Africa a committee appointed in 1928 to inquire into

¹ See Chap. XVIII, p. 1217.

the training of natives in medicine and public health recommended¹ the provision of facilities at the University of Witwatersrand, in a non-European branch of the existing school, in which Africans would receive the same training as Europeans. A pre-medical year was to be spent at the South African Native College, students to be admitted from outside the Union, and loans provided from native funds to assist them to take the full course. This scheme has since been modified. By the aid of a large grant from the Transvaal Chamber of Mines a start was made in 1935 with the training of 'medical aids' at the South African Native College² in a course lasting three years, preceded by a preparatory year's training in science, and followed by a year's practical hospital and public-health training at Durban. The courses are designed for the purpose of providing assistants for District Surgeons in the reserves and other native areas. As such they should supply a definite want. Some of these assistants should be available for service in 1940.

Both Yaba and Mulago would appear to contemplate that, at some future date, they will be equipped to train fully qualified African practitioners,³ though at present they have a more limited aim. The Yaba Medical School was founded in 1930 and a system of training based on that of Great Britain was instituted in 1934. After a five-year course successful candidates will be registered as medical assistants, and will be entitled to practise medicine, surgery, and midwifery in the government medical service. An assistant who has been registered for at least three years, and who has passed a further examination, can be granted a diploma of licentiate and be registered as a medical practitioner in Nigeria. The training staff consists of a Superintendent of the Medical School and a teacher of pharmacy, but a prominent part is also taken by the staff of the African hospital at Lagos and of the research laboratories at Yaba.

The institution at Mulago in Uganda is intended to make provision for the needs of East Africa generally. A school for the training of African assistants in medicine and surgery was started

¹ U.G. 35, 1928.

² See Chap. XVIII, p. 1218.

³ *Report of the Commission on Higher Education in East Africa*, Colonial 142, 1937, pp. 87, 95 ff.

at Mengo Hospital by the Church Missionary Society in 1913. After the War it was closed until 1921, when it was revived and continued under a Medical Officer appointed by the Education Department. The object of the school was to bring the higher medical education of Africans up to a standard approaching that of the Indian sub-assistant surgeons. The course was of four years' duration, but in 1927 it was extended to five years and in 1936 to six, including the two years of pre-vocational science at Makerere College. The instruction is given by officers of the Medical Department. The number of students in 1937 was thirty-one; of these twenty-five were natives of Uganda, one was from Kenya, three from Tanganyika, and two from Zanzibar. It is considered that in some ten years' time the number of students will reach about 100, and the school will produce not less than thirty qualified African medical students annually.¹ A joint East African Examining Board in Medicine conducts examinations in pre-vocational science and in more advanced subjects, culminating in a final examination for a medical diploma. The institution will form part of the Higher College which it is proposed to start at Makerere, and the general standard of teaching is being raised so as to secure recognition of the Higher College Diploma from the General Medical Council. It is held that some of the diplomates are capable, under supervision, of running small medical stations and hospitals. After qualification the assistants work for a year as house physicians or house surgeons before taking up their work in the government services. In Uganda a system of registration of medical assistants was started in 1931.

The *École de Médecine de l'Afrique Occidentale Française* at Dakar was opened in 1918.² It may be said to be the most successful and certainly the largest effort in Africa to provide a colonial medical and health service with adequate African assistance; since its foundation the school has provided over 400 medical assistants with an acknowledged standard of efficiency. The training is aimed solely at providing assistants for the state service. It is only in France that full medical degrees can be obtained, and,

¹ *Ibid.*, p. 95.

² F. Sorel, 'Les écoles de médecine de l'Afrique française,' *Bruxelles-Médicale*, vol. 17, no. 43, 1937, pp. 1526-35.

generally speaking, the *médecins auxiliaires* trained at Dakar are unable to make a private practice; provision has, however, been made for those of an exceptionally high standard to obtain permits to practise privately, but only after service for the state, and no such permits have yet been given. Prospective *médecins auxiliaires* spend a special course of two years' general education at the *École William Ponty* on the island of Gorée. Selected candidates then take a four years' training at the medical school; more than a hundred students follow the course at one time, and include some half-castes. They obtain their clinical training at the general hospital, the maternity institution, and the *Polyclinique* to which reference has already been made.¹ About twenty-five students pass the final examination each year and then follow a course of practical work in hospitals before they pass into the government service. Refresher courses are given at intervals, and a further examination is imposed after ten years' service.

The advanced training of Africans as medical assistants or auxiliary doctors has only of recent years been recognized as a necessity in the Belgian Congo. A government school for the training of medical assistants was opened at Léopoldville in 1936, and a similar school is to be opened at Kisantu under the direction of *Fomulac*.² The course is to last for six years, two of which will be spent in practical work in the laboratories and centres of the *Assistance Médicale aux Indigènes*.³ The standard of teaching and of previous education is to be equal to that of the Mulago and similar schools. By 1937 five pupils had completed their first year with success.

The education of the subordinate staff, such as male and female nurses, dressers, and hospital orderlies, does not necessarily demand a special institution since training facilities can be made available at hospitals; it is, however, an advantage to have a special school for some of the more skilled branches, such as dispensers. A visitor to African medical institutions will find a great variety of practice in the training of subordinates, as well as a somewhat bewildering variety of nomenclature; a 'dispenser' is in some places a ward

¹ See above, p. 1173.

² See above, p. 1178.

³ See Ordinance 38 / Ter. Hyg. of March 12, 1936, for conditions governing the school.

orderly, placed in charge of an outlying dispensary; in others he is a hospital dispenser, who has been trained for the purpose in a special school. There is also some variety in the educational standards accepted for entry into the subordinate services; in some quarters it is held that more suitable material is to be found in the product of the primary school than in those who have passed through higher classes. There is a very general agreement as to the efficiency attained by medical subordinates in certain classes of work, such as the routine use of the microscope, and the administration of injections. Generally speaking, however, the character of the existing medical subordinates necessarily reflects the fact that there is still, in most parts of Africa, a low standard of general education, and efficiency can only be maintained by the exercise of a close supervision.

In remarking on the facilities now existing for the training of subordinates, it must be remembered that a great deal of medical education has been, and is still being given by the missions. The training given varies from a four-months' medical course in connexion with a well-organized hospital to that given by individual mission doctors or nurses at small centres; but as future development in medical education depends to a great extent on an expansion of the state services, the following account aims at giving an outline of these, and necessarily omits reference to much other important work.

In the Union, training is mainly given by missions for subsequent employment in their own hospitals and dispensaries. The committee of 1928, referred to above, recommended that the state should give training to natives as health assistants and nurse-midwives. In the High Commission Territories training has been started with the aid of a grant of £10,000 made by the gold-mining industry in May 1934, but there is, at present, no scheme in any of the three territories for the organized training of Africans as medical assistants or health workers. In Bechuanaland a few Africans of both sexes are trained each year as nurse-aids and dispensers at Serowe and Lobatsi Hospitals; some of these proceed to outlying dispensaries, where the intention is that they should give simple medical treatment and instruction on hygiene in the neighbouring villages. European sanitary inspectors are to train

a few Africans in health work. In Swaziland the training of female nurses is carried out at the hospital at Bremersdorp, and the first eight probationers completed a year of training in 1936.

In Southern Rhodesia the training of native medical orderlies at schools attached to the Salisbury and Bulawayo Hospitals has been developed in recent years in connexion with the extension of the medical services to native rural areas. No provision is made for the training of 'medical aids'. Orderlies are posted to the medical units to take charge of sub-hospitals or dispensaries. Schemes for the training of native women have been prepared, including the establishment of a training school for midwives in connexion with the Bulawayo Hospital.

In Northern Rhodesia the training of Africans is admittedly inadequate, and the extension of medical and health services in the rural areas is impeded by lack of subordinate staff.¹ A number of African orderlies have been trained in the past at both government and mission hospitals, but the backwardness of general education has made it difficult to find suitable candidates for serious training. A government course started in 1936 produced fifteen orderlies who were trained for one year only in view of the urgent need for subordinate staff. Future courses are to be for two years. The estimates for 1938 provide for a training school which will take some time to produce results.

In Nyasaland the training of subordinate staff is also backward. The Church of Scotland Mission at Blantyre provides a course of training for midwives and for African hospital assistants, and the majority of assistants employed in the government service are obtained from this source. The government now intends to train male nurses, dresser-dispensers, and health assistants at the African hospital at Zomba, but the higher grade assistants will continue to be trained at Blantyre.

In Tanganyika the training of African dispensers began in 1926. Courses, divided equally between theoretical and practical work, are given at various medical centres, followed, in some cases, by a course lasting three years at Dar-es-Salaam. In 1936 sixteen students were in training at the end of the year. The training aims at meeting the need for a large number of assistants capable of

¹ *Report*, op. cit., Colonial 145, 1938, pp. 292-3.

diagnosing and treating ordinary minor ailments, and of recognizing serious cases which require to be sent to the larger hospitals for treatment, and who can also supervise the tribal dressers employed by the native authorities. Scholarships are provided to enable exceptionally promising pupils to enter Mulago. The training of English-speaking sanitary inspectors at Dar-es-Salaam for urban work began in 1921, and of others speaking the vernacular only in 1925. In 1935 a training centre for tribal dressers was opened in connexion with Mwanza Hospital. The course lasts eighteen months, and eighteen students have completed the first year's training. Schools on a smaller scale, where the course will last three years, have been built and equipped by the native administrations at Bukoba and Musoma, and ten pupils were in training by 1936; there appears to have been in this case a certain duplication of effort. Tribal dressers staff some 300 dispensaries maintained by the native authorities, and though the large number opened is striking evidence of the desire of the tribesmen for medical treatment, the demand could only be met by sending out men who had had no definite training or at the most a few months only. The institutions opened at Mwanza and other centres have for their object the improvement of this system in the Lake Province, but such centres are clearly needed also in other parts of the territory. The dispensers are explicitly instructed to attempt to treat only minor ailments; they are required to encourage cases beyond their powers to attend a dispensary or hospital.¹

In Kenya since 1930 much attention has been given to the training of subordinate African staff, and courses of training are provided for hospital assistants, male nurses, compounders, and welfare workers. The Medical Training Dépôt in connexion with the native hospital at Nairobi had 21 learners in training at the beginning of 1936, and 12 others finished their training. Up to 1936, 37 hospital assistants and 11 compounders had been trained, and are stated to have reached a high standard. The course of training for Africans in health work at the Jeanes School was discontinued in 1936, partly for financial reasons, but more especially as it was felt that better results might be obtained by practical training in the field under European sanitary inspectors. There

¹ *Annual Medical and Sanitary Report, 1934*, p. 10.

is no institution for the training of African women in nursing, owing to the lack of a sufficient number of girls with an adequate elementary education; it is hoped, however, that training facilities may shortly be provided.

In Uganda, junior nursing orderlies receive one year's training at Mulago, followed by a year under a European nursing sister either there or at one of the district hospitals, after which a senior course may be taken involving another twelve months' work. Girls are in training at Mulago Hospital and at the mission hospitals, and take the same course and examinations as the male nurses. Two mission schools train midwives; the course consists of theoretical and practical training for two years. A special course for training Africans as sanitary inspectors was begun at Mulago in 1936, and sanitary overseers, with lesser qualifications than the inspectors, are trained by selected European sanitary inspectors in the elements of rural sanitation. After completing the course the overseers are attached to the native authorities. A course for training African artisans in simple well-construction and the protection of water supplies was begun in 1935.

In Nigeria nurses, dispensers, and other subordinate African staff are trained at several of the African general hospitals. The course for nurses is three years; after a preliminary theoretical training for six months most of the instruction is given in the wards and out-patient departments. For midwives and infant welfare workers the length of training is two and a half years, including the same six months' preliminary course in general nursing as the nurses receive.¹ Dispensers are mostly trained at the School of Pharmacy at Lagos, and a three-year course is followed by practical training at hospitals. Laboratory attendants similarly have a three-year course with a fourth year where possible. The training of sanitary inspectors has been developed especially in Southern Nigeria, and a centre at Ibadan was completed in 1932, with assistance from the Colonial Development Fund. The course is two years in length, and up to 1936 some twenty-five Africans passed through the school.

In the Gold Coast midwives are trained at the Accra Maternity Hospital, and nurse-dispensers for the rural areas at the Gold

¹ *Training of Subordinate Staff of the Medical Department, 1930.*

Coast Hospital. Four of these nurse-dispensers complete their training each year. It is anticipated, however, that in the absence of trained medical assistants, for the training of whom the nearest centre is Yaba, an expansion of the qualified medical staff will be necessary to provide adequate supervision, if these dispensers are to form health centres in all the rural areas. It is also proposed to provide a high grade of African health visitor, who will be a trained nurse and midwife and will have undergone a comprehensive course of hygiene.¹ A school for sanitary inspectors was reopened in Accra in 1934; the training of village sanitary overseers was started in 1935 by health officers in Kumasi and Tamale.

In Sierra Leone the Connaught Hospital at Freetown trains nurses, midwives, and dispensers, some of whom practise privately, but the majority stay in the government service. Sanitary inspectors are trained in Freetown, and recently refresher courses have been inaugurated. Facilities for training midwives and health workers will be extended when the new maternity hospital at Freetown is completed: a maternity training centre and an infant welfare centre will be included in the hospital, towards which the Colonial Development Fund is contributing,² and it is hoped that the work will be completed in 1939.³

There are no schemes for the systematic training of African subordinate medical staff in the Cameroons or Togoland under British Mandate, or in Gambia; they depend on neighbouring colonies or on such training as may be given in local hospitals.

In French West Africa the *École de Médecine* at Dakar provides courses of three years in dispensing and midwifery, and two years in district nursing, during which students spend a large part of their time in practical work at the *Polyclinique* and in native hospitals.⁴ Special training in connexion with the *équipes de prospection et traitement* is given to Africans at Ouagadougou.

An *École des Aides de Santé* was started in 1932 at Ayo in the Cameroons under French Mandate.⁵

⁴ See above, p. 1172.

⁵ F. Sorel, *op. cit.*

In French Equatorial Africa the present large subordinate staff has been trained in the hospitals, dispensaries, and health centres. In future it is proposed to form a centre for medical studies in connexion with the hospital at Brazzaville, consisting of a school for the training of *médecins auxiliaires* and a maternity school,¹ and in 1935 the *École Edouard Renard* at Brazzaville was reorganized to provide the pre-vocational training for the students.

In the Belgian Congo the schools at Léopoldville and Kisantu² have trained a number of medical subordinates and, in addition, a number of institutions have for some years trained male nurses, health assistants, midwives, and assistant nurses (*aides-infirmiers*).

The principal hospitals serve as training grounds for other subordinate staff as in the British and French territories, and the missions and auxiliary services train their own subordinate staff. For example, the *Croix Rouge du Congo*, in its work in Uélé, specializes in the training of nurses and midwives, usually the daughters of chiefs, who are encouraged to marry members of the subordinate staff and settle in the rural areas. As is subsequently noted, the general use of the Belgian religious orders for nursing and other offices in medical institutions is a prominent feature of Congo policy. At Astrida, in Ruanda-Urundi, a school for training native auxiliaries was started in 1937 and fourteen pupils passed the first entrance examination.

It will have been seen that at one time the training of medical subordinates was left largely to the missions, or to the discretion of individual officers in charge of hospitals or laboratories. In a number of territories the training of medical assistance of this class is now being systematized, though in some, such as for instance the Rhodesias and French Equatorial Africa, the matter is given less attention. Even if, as suggested earlier in this chapter,³ the African of this class is at present seen at his best in purely routine work, there is a wide and very useful field for his employment; it is clear, moreover, that in some cases it is necessary to take more active steps to educate subordinates such, for instance, as those employed in the native administration dispensaries of Tanganyika,

¹ *Discours d'ouverture du Gouverneur Général de l'Afrique équatoriale française au Conseil d'Administration*, 1936.

² See above, p. 1180.

³ See above, p. 1187.

who have been given responsibilities which they have not been trained to discharge. The position is one which seems to require some further study by the administrations concerned. It is especially necessary to consider the possibility which each territory offers of giving training to women and girls, through the employment of village health nurses. There are already a certain number of such nurses employed in some territories; their work lies in giving instruction in ante-natal and child-welfare work, and in domestic dietary and cooking. In Africa the employment of women on work of a public nature is not subject to the same difficulties as in many parts of the East; women have their own position in society, which, in West Africa at all events, seems to give them considerable independence, and extends to the right of possessing property of their own. It is nowhere more true than in Africa, that if social environment is to be altered, it is primarily the women to whom the necessity of change must be brought home. But if women are to be more largely employed on work of this class, it is also essential that the education of African girls¹ should be such as to supply the necessary number of recruits.

A problem which has become apparent is that, as advanced medical text-books are designed for European students they are to some extent unsuitable for those who will work in African conditions; also African subordinate staff is often necessarily isolated from immediate contact with superior officers, and has frequently to assume serious responsibilities. Handbooks in simple language for consultation and study would therefore appear to be of great value.²

IX. HEALTH POLICIES IN AFRICA

(a) *The Social Aspects of Health*

It is clear that poor physical conditions, due to poverty and environment, play an important part in the story of disease and sickness in Africa. The gradual realization in other continents of the relationship between environment and health is reflected in the growth of a similar outlook in Africa. In Europe this new outlook has brought changes in two particular directions. In the first

¹ See *Report of the Commission on Higher Education in East Africa*, Colonial 142, 1937, p. 71.

² See Dr. W. K. Connell's *Surgical Handbook for Hospital Assistants in the Tropics*, 1938, which has this aim.

place, the state's liability for the care of the sick worker has been accepted; and it is well that acknowledgement of this principle in Europe has come at a time when medical policy in Africa is still fluid. In the second place, the responsibility of environmental conditions for many diseases has been recognized, so that the improvement of working and living conditions, and education in simple measures of hygiene, take a prominent place in the programme of health organizations. This change of outlook has, moreover, coincided with the very general recognition that measures which lead to an improvement in health and an increase in population are likely to have a direct influence on African economics. It is, indeed, not too much to say that the larger industrial concerns have in some areas anticipated recognition by the administrations of the need for extending public health measures. They have realized that, low paid as the African labourer may be, an ailing and inefficient employee is expensive and wasteful. The lead given by some of the larger industrial concerns¹ in investigating the basis of a health dietary, and in measures taken for the promotion of health conditions among employees and their dependents, has been of definite benefit in the formation of a state health policy for Africa.

In the earlier days of colonial development, medical authorities tend, often perhaps unconsciously, to divide themselves into two groups. The first, anxious for the credit of European systems of medicine, concentrates its attention on extension of its hospital work, the standards of which it can ensure by its own supervision. It has some suspicion of an expansion of medical facilities which would involve entrusting to partially trained or unqualified hands the application of European methods in medicine and surgery. The second group does not question the value of hospital work; it acknowledges, in particular, that it would hardly have been possible to convince the native of the benefits of European medicine, if it had not been possible to exhibit to him the achievements of European surgery. But it is impressed with the narrowness of the field which the hospital under strict European supervision can command; it believes that, even if many risks and perhaps failures have to be faced, much positive good can still be achieved by a

¹ See Chap. XI, pp. 673, 680.

wide extension of dispensaries under partially qualified assistants, especially if care is taken to see that the latter pass on to the major institutions any cases which are beyond their control; and it adds that, in any case, it is necessary to maintain an extensive organization for dealing directly with epidemic disease, both on the preventive and curative side. Such an establishment must inevitably contain a considerable proportion of partly qualified men. The difference of view is sometimes expressed as a conflict between the advocates of preventive and curative medicine. That expression, however, overstates the actual facts; it is not justifiable to represent medical opinion as divided into two camps on the subject; often the difference of views is, in practice, only one as to the best manner in which a medical administration can expend the narrow resources at its disposal.

It has been seen that the French are content to maintain a few first-class hospitals, and for the rest to rely on the 'medical centre' with its attached dispensaries, and on mobile detachments for dealing with the epidemic diseases. The expenditure on the building and general equipment of the less important medical institutions is relatively low; the food, as already remarked, is often supplied by the family of the patient. This is far from impairing the popularity of the institution with Africans; and, indeed, it must need a great deal of skill and personal sympathy on the part of the European staff to overcome the impression left on the African by the discipline and the isolation from friends which is the rule in many of the British hospitals. The French appear to lose, on the other hand, by the fact that many of their doctors, being on the military cadre, have little incentive to study African conditions, and that administrative policy limits the expansion of medical facilities by refusing to open dispensaries where they cannot be supervised by a French qualified medical man. The Belgian system relies largely on the application of intensive methods to 'clear up' affected areas. It is a system which devotes its efforts in the first instance to dealing with certain types of disease and in particular with sleeping sickness. It maintains at the same time the normal hospital system, in which it makes a general use, as it does in education, of the Belgian religious orders to superintend nursing and the like. The system has much that is attractive,

in particular, the completeness of the study made of the areas under 'intensive' treatment, but it will not be possible to judge of its efficacy until experience has shown whether the 'clearing up' of the affected areas has a lasting effect.

The British territories have hitherto normally relied on a system of hospitals with their outlying dispensaries, rather than on the more elastic method of the mobile medical detachment, though, of course, the latter has been utilized to deal with outbreaks of epidemic disease, and it has been seen that Nigeria now contemplates the use of a system resembling that of France and Belgium to deal with areas affected by sleeping sickness.¹ There has been incurred on some of the British hospitals² an expenditure which can perhaps be justified in some cases by the fact that the hospitals are meant to afford clinical material for medical teaching; but in others the money expended might perhaps have been devoted with greater advantage to providing more extended areas with medical facilities of a much simpler type. It would clearly be unjustifiable, in the absence of any comprehensive expert inquiry on the subject, to attempt any generalization as to the relative merits of the systems employed by different countries; but quite apart from any suggestion of comparison, it is difficult not to desire to see in some of the British territories more evidence of the spirit which shows itself in a direct attack on the health problems of the people. In Africa it is not enough to multiply facilities (however good in themselves) for the treatment of such individuals as apply for relief; disease of the type which causes most mischief in Africa is generally a mass infliction, and must be attacked in the mass.

The adjustment of the balance between the improvement of health conditions through social welfare schemes and the treatment of disease through the usual agencies of medical science presents a difficult problem, the solution of which will necessarily vary in different territories. Public health work has been so commonly regarded as a specialist interest, that it is not surprising to find this outlook reflected in the history of medical services in British colonies. When the need for sanitary services became apparent, an additional division of the Medical Department was created, and in several territories the divisions are still separate.

¹ See above, p. 1168.

² See above, p. 1169.

It is, however, increasingly recognized that the two are inseparable, and that it is the chief task of a medical department to secure a rising standard of physical fitness among the population at large.

At no period which we can now envisage is it likely that the progress made by preventive work will enable us to dispense with hospitals; all that can be claimed is that they should not now be allowed an undue share of the provision made for the health services.

(b) *The Co-ordination of Welfare Departments*

Emphasis on the social aspects of health implies, as a corollary, that improvement in general health can only be achieved by effective co-operation between the various state services which affect the environment of the people. Expressed in more concrete terms, this involves, for example, that the improvement of nutrition must be recognized as the concern of the Education and Agricultural and other Departments as well as that of the health services. The medical authorities can do little more than indicate what dietary deficiencies exist, and it is for other departments to devise how these deficiencies may be made good, or to induce the people to change their habits of eating. Emphasis on any one aspect of social welfare cannot produce permanent results unless proportionate attention is devoted to the others, and the policy of the Medical Department requires close co-ordination with that of the other government departments, and also the private agencies, such as missions or commercial companies, which are concerned with the development of the country. Certain areas have adopted, with good results, the institution of development committees consisting of the heads of various departments of the social services; an example of this is the Nyasaland Native Welfare Committee formed in 1935, consisting of representatives of the Administrative, Medical, Agricultural, Forestry, and Education Departments.¹

(c) *Health Education*

It has been seen that the French and Belgian administrations have recourse to the use of a measure of compulsion to enforce compliance with medical requirements in certain classes of cases.²

¹ See *Report of the Nyasaland Native Welfare Committee, 1936*.

² See above, pp. 1141, 1176, 1177.

On some occasions British administrations have found it necessary to take similar powers.¹ There is in Africa little of that opposition to the application of modern medical science which arises from attachment to a recognized system based on different principles, such, for instance, as is felt for the *Unani* system of medicine by many Moslem peoples in the East. On the whole such compulsion as has been applied seems to have aroused little feeling, and it is difficult to see how some of the graver diseases can be effectively controlled without its use. The most difficult problem of the health services does not, however, lie in enforcing anti-epidemic measures, but in persuading Africans to adopt the recognized principles of hygiene as part of their social habit. Not all those who practise native medicine in Africa can be dismissed as witch-doctors; many are much respected, and it is indeed possible that a study of the herbs used by some of them might add to the list of remedies, such as quinine, which the pharmacopoeia owes to primitive medicinal practices. It remains, however, the fact that the sanitary services must now undertake an education in health matters which will replace the advice given by native practitioners and also many of the prescriptions of African custom, as conveyed in initiation ceremonies or the like.

Considerable advantage has been taken in Africa, as elsewhere, of the opportunities which school education affords for teaching the principles of hygiene, whether as part of the school course, or by means of institutions such as the Junior Red Cross. Experience shows, however, that the educational process needs to be carried on through adult life. Many methods, old and new, have been and are being tried in Africa.

The value of the public-health nurse living among the people has already been mentioned.² Health displays are said to extend knowledge of health matters, and can be held in connexion with agricultural or other shows or form travelling units providing health talks in the vernacular. Posters, in connexion with these shows or at hospitals and dispensaries, and literature³ are also said to be of value, and in Tanganyika letters addressed by the

¹ See above, p. 1132.

² See above, p. 1193.

³ See *The Book of Civilization*, arranged by Dr. A. R. Paterson, Part I, 1936; Part II, 1938.

medical authorities to mothers about the feeding of infants with solids are said to have been effective.

The cinema and broadcasting have their possible uses, which are discussed elsewhere.¹ They may possibly make a greater appeal to an audience which has had some education than to more primitive people.

The British Social Hygiene Council, which receives an annual grant from the Colonial Development Fund, has a library of educational films which are lent for exhibition in parts of Africa, and by means of conferences enables social hygiene workers from different parts of the Empire to keep in touch with each other. It also assists the campaign against venereal diseases by publishing a series of handbooks on biological teaching.

(d) Control of Migratory Labour and Travellers

It is said that in a population free from interference from outside sources, a balance would arise between the general resistance of the people to parasitic disease and the pathogenicity of the parasites. The balance which may have existed among African tribes is, however, liable to be upset by the contacts following from improved transport and the movements of labourers. Diseases have been introduced to which the African was formerly a stranger and to which he had developed no resistance, and fresh strains of parasites cause attacks of diseases to which he was formerly immune; further, Africans now contract diseases common to temperate zones, and it is possible that the intensity of these is increased owing to lack of acquired immunity, the low sanitary standards, or low resistance resulting from malnutrition.

Regulations regarding diets and living conditions are imposed with some measure of success on employees living in large compounds, but health control of casual labour presents a more difficult problem, especially where the demand for labour is seasonal. Africans travelling to places for work are often under-nourished, and readily fall victims to infection, and it is believed that cerebro-spinal meningitis and influenza, in particular, are spread by migrating labour, while travellers from sleeping sickness areas are liable to infect tsetse-fly in areas where the disease has not hitherto

¹ See Chap. XVIII, pp. 1297-1305.

been found. Similarly, new strains of malaria parasites may be introduced into endemic areas where the inhabitants are immune to the local strain.

Again, the returning worker may introduce to his home disease such as tuberculosis. Mechanical transport is easy to control, but foot transport presents greater difficulty. Successful control depends on the immediate notification of disease outbreaks from territory to territory, combined, where possible, with a system of medical passports recognized on both sides of the boundary. At present medical passports issued in one territory are often not recognized in neighbouring territories, and there are frontiers where no international control exists. Medical passports, again, are frequently impracticable in African conditions, where boundaries are extensive and medical staff insufficient to ensure proper control; hence it seems that the system must for some time yet be confined to limited areas. Medical passports are in force on the border between Uganda and Tanganyika Territory, west of Lake Victoria, to prevent the northward spread of the *rhodesiense* type of sleeping sickness, and the system is said to work satisfactorily, but mainly owing to the fact that the Kagera river forming the frontier limits the movements of people to four ferry crossings. On the other hand, while the Congo Government does not permit immigration from Uganda without a certificate that the immigrant is free from sleeping sickness, people on both sides of the border cross the river frequently and control clearly cannot be made effective in the absence of a large staff of inspectors.¹

(e) *The Problem of Payment for Treatment*

The problem of securing the widest possible use of the health services is closely connected with the question of payment for treatment, and the encouragement of private practice among Africans will also depend to a great extent on the policy adopted.

It has been seen that the present policy in the French colonies is to educate only that number of 'auxiliary' medical men which is needed for the service of the state. British policy, as is shown in Nigeria, contemplates educating medical men for private practice,

¹ *Report to the League of Nations on Tanganyika Territory*, 1937, p. 94.

and the South African training of 'aids' has the same object in view. A state hospital system, however widely extended, fails in one respect, namely, that it does not provide consultants able to visit patients in their own homes; and experience elsewhere shows that a demand inevitably arises either for private practitioners, or for the grant of liberty to hospital or dispensary doctors to take fees as private consultants. If this be granted, there inevitably arises either in fact, or in the impression conveyed to the public mind, a conflict between the duties for which the state and the patient are respectively paying. Both for this reason, and also on more general grounds, it seems preferable to encourage the growth of an independent medical profession.

The right of private practice among doctors who are members of a state service presents many difficulties. Theoretically it appears unsuitable for members of the British Colonial Medical Service, for example, paid for full-time government duty, to devote even a small proportion of their time to private work, but it is often difficult to maintain this attitude when no other medical aid is available. The present policy is to reduce, and possibly remove, this right, as private practitioners increase in number.

In the case of African patients, the policy regarding payment, in return for medical services provided by government or missions, varies in different territories. In the French colonies no payment is asked in return for medical attention save in exceptional cases where patients can obviously afford it. It is, however, usual in the smaller French hospitals for food to be provided by the patient's relatives and not by the government, so the costs of hospital upkeep are not heavy in respect of these items. In Togo under French Mandate payment is, however, required and a scale has been laid down of 1 franc for a consultation, and operation fees of 5-20 frs.; in-patients pay 1.50-3 frs.¹ In the Belgian Congo infectious diseases, including sleeping sickness and all epidemic and endemic diseases, are treated free. In the case of other diseases and of accidents and most surgical cases, some payment is expected from patients who can afford it, to cover the cost of at least part of the materials used, but no private fee may be

¹ *Arrêté* of January 19, 1923.

paid by natives to a doctor in the state services or under organizations such as *Foréami* or the *Croix Rouge*. Wherever possible the relatives of hospital patients are expected to contribute food for their support. In the British colonies it is usual for natives to receive free attention, but in many cases those who can afford to do so are required, both by government and mission institutions, to make small payments for treatment or medicines. These payments are required in Uganda, for example, except in cases of notifiable infectious diseases or of indigent persons and prospective mothers; revenue from this source comes particularly from patients having salvarsan injections. When possible, patients at hospitals or dispensaries in Uganda pay a sum not exceeding two shillings a week, but patients in private wards pay as much as one shilling a day. In Basutoland the African out-patients departments charge one shilling for each attendance, but in-patients receive free treatment.

In support of the view that treatment should be gratuitous it is said that in many parts of Africa medical attention is one of the few obvious returns which the African sees for payment of tax. Furthermore, it is held that free treatment would favour the declaration of diseases which might otherwise be hidden. On the other hand, it is held that Africans are more likely to appreciate medical aid and come for treatment with greater readiness if the service is not taken entirely for granted; Africans, like some Europeans, are said to appreciate benefits received in proportion to the amount they pay; thus an expensive injection is thought more effective than one costing less. It has been suggested that difficulties might be avoided by means of a simple co-operative system in rural areas, whereby small fees were charged on a regular basis and responsibility for payment rested with the local native authority or the headman, a certain proportion of the poll tax being considered as an insurance contribution on the lines of health insurance in certain European countries. It would be of interest were an experiment made on these lines; the suggestion is open, however, to the objection that the system of collection partakes so much of the nature of a tax as to lose any voluntary aspect. It would be liable to be viewed merely as an addition to the ordinary poll tax.

(f) Organization of Medical Research and Health Statistics

There is at times a tendency to apply the term 'research' to laboratory work of a more or less routine nature. Work of this class is of special importance in Africa, since tropical disease is frequently dependent on laboratory tests for its diagnosis; but it is more convenient to confine the use of the term 'research' to those activities which involve a definite element of new inquiry. In some instances investigation is undertaken by officers who are detached from routine work for this purpose; in others, and in particular in some of the smaller administrations, it is carried out by laboratory officers in such time as they can spare from their routine work. An indication has been given in the preceding sections of the institutions already in existence in Africa where investigation is being carried out. While in the French territories some degree of co-ordination is maintained through the Pasteur Institute, each laboratory in British territories is, in effect, an independent unit. Here the problem which arises is not merely that of the possible overlapping of work, though such overlapping undoubtedly occurs, but of finding a system by which, instead of the subject of inquiry being left largely to individual discretion, authority can be exercised to direct efforts towards the matters in which investigation is generally felt to be most necessary. The question will form the subject of a later chapter in this Survey;¹ it is sufficient to note here the opinions expressed at various times when this matter has come under discussion.

In East Africa the need for greater co-ordination has been felt, and an attempt to secure it has been made, by the holding of Research Conferences at Entebbe in 1933 and at Entebbe and Nairobi in 1936, while even earlier arrangements had been made to centralize the production of calf-lymph and stock vaccines required by Kenya and Uganda. The Research Conferences, which were intended to co-ordinate research and to prevent simultaneous investigation of problems on identical lines, have shown the difficulties inherent in organizing research under present conditions when responsibility is not centralized. For this reason the Standing Medical Research Committee for East Africa, which was

¹ See Chap. XXIV.

set up on the recommendation of the Research Conference in Nairobi in 1936, has advised that a medical research fund contributed to by all the East African governments and controlled by trustees should be formed, and that a Director of Medical Research for East Africa should be appointed to organize research in those territories. The scheme should be followed logically, if successful, by a similar organization in West Africa. It has been suggested that it may eventually be found desirable to centralize all colonial medical research services in association with the London School of Hygiene and Tropical Medicine. This would then allow of members of the staff of that School being seconded for service in territories abroad with gain not only to themselves, but also to the territories they visit and to the students whom they return to teach.

Medical research in Africa is concerned with many problems of the greatest importance. Some of these can be investigated in Europe as well as in Africa, others can only be investigated in the countries where they occur. With limited finance and equipment, it would appear reasonable that research in Africa should as far as possible confine itself to the second of these groups, leaving the first group to be dealt with by the large laboratories at home. It seems desirable also that research in Africa should devote itself primarily to problems of immediate practical importance, and to the task of adapting discoveries in Europe to African conditions.¹

There are final points of considerable importance, to which some reference has already been made in the chapter dealing with population records. No administrator can adequately determine the value of his health organization unless he has reliable vital statistics by which to measure it. It is obvious that the figures available in Africa are not only inadequate but often misleading.² Data collected from hospital returns might be expected to be accurate, but careful inquiry into the method of compiling them is necessary, and still more so into the qualifications of the person making diagnoses. Thus in certain colonies the return of cases of disease given in the Annual Reports includes a high percentage (50-70 per cent.) diagnosed by medical orderlies in charge of dispensaries with inadequate medical knowledge. Other colonies

¹ See also Chap. XXIV.

² See Chap. IV, p. 127.

return dispensary figures separately, but it may be accepted that even in district hospitals not every diagnosis is made by a qualified doctor, and substantial inaccuracies occur. So useless have these annual returns seemed to those whose duty it is to make them, that a recent conference of Directors of Medical Services in East Africa advised their replacement by a simple table giving returns according to the main groups of the International List of Causes of Death, and only specifying certain diseases which have a peculiar importance from the epidemic point of view. Further consideration of possible lines of improvement is clearly needed.

It is also clear from the statistics given in connexion with the organization of health services that large numbers of the African people, if not the majority, are still beyond the reach of medical and health services in the ordinary sense.¹ It is safe to conclude that in many districts such services consist of the limited facilities of a mission dispensary or a small supply of medicines and 'first-aid' material at a government station, possibly dispensed by a half-trained African orderly. Village sanitation does not exist in many areas—the sole sanitary measures are those brought about by the District Officer, who may insist on villages being kept clean, or advise native authorities to make rules to this effect and punish offenders. Most ordinances prescribing the powers and duties of native authorities allow for rules requiring the reporting of deaths, and it is usual for deaths from unknown or suspicious causes to be reported to the District Officer, who by this means may detect the presence of an unusual disease or an epidemic. The District Officer is, indeed, the channel through which the presence of such disease becomes known to the medical authorities, and in few rural areas does there appear to be any system of detection of disease by qualified persons that can be said to be effective. Opinions with regard to the incidence of the more typical African diseases may vary, but it is clear that in many rural areas the mortality from malaria is high and that sources of malarial infection exist in most villages; that intermittent fevers are prevalent; that helminthic diseases are almost universal, the filthy state of the villages being conducive to their spread; and that few village

¹ A comparison of these statistics with the Population Tables in Chap. IV, p. 108, might usefully be made.

children are free from sores, and many adults are under-nourished and have little stamina. An examination of a typical Central African village would show that the sick, especially old persons and children, are neglected or unwisely treated, the elements of hygiene are lacking, the wearing of unhygienic and dirty clothing is usual, food is prepared in dirty vessels, flies swarm on garbage thrown near the village, and huts are often unswept and infested with parasites. The conditions of urban compounds are often criticized, but they may be compared favourably with those in rural areas. Little can be done to improve such conditions until the Africans themselves are conscious of a need for betterment, or at least until the native authorities themselves are aware of their responsibilities, and the health services have sufficient staff at their disposal to enforce sanitary measures.

CHAPTER XVIII

EDUCATION

I. THE GENERAL NATURE OF THE PROBLEM

IN a discussion of education in Africa it is inevitable that attention should be mainly directed to native education. That of Europeans has its own problems, which will claim some notice, but they can for the most part be solved in accordance with precedents which exist elsewhere. The problem of native education is peculiar because the circumstances of an undeveloped race are fundamentally different from those of a homogeneous and relatively static modern community. In such a community, the chief function of education is to maintain the continuity of culture by transmitting to successive generations not only accumulated knowledge but acquired standards of value and conduct; in Africa education is, and is intended to be, an instrument of change.

The African has his own methods of education in the form of character training and instruction in crafts, or, in the case of girls, in the duties of domestic life. Initiation ceremonies or 'regimental training' are usually the culminating point, and the system is directed to fitting the youth to take his place in the traditional life of his group: 'social obligations form the core of all teaching given by tribal elders.'¹ Education, as we now see it, has a new direction. The environment of the African is being rapidly modified by influences to which he has hitherto been a stranger, and his school life must therefore be designed not only to equip him to deal with his existing environment, but to fit him for the new conditions which he will have to face and to help him to take his own part in shaping those conditions. The method will be new, for it must be institutional, and cannot follow the traditional form of tribal instruction. Accordingly, the African child will be introduced to a world of thought, of achievement, and of conduct outside the experience of his parents; this access to new ideas is bound to make a break in his life, however much the educationist may wish to respect native tradition. What is to be the content of the instruc-

¹ W. D. Hamblly, *Origins of Education among Primitive People*, 1926, p. 412.

tion offered? How far and how fast can the process go? How is it to be related to the other influences which are transforming African societies? In so far as these influences are the product of conscious purpose, how far can they be made to form part of a unified scheme of development based on co-operation between the various services of government? What is to be the life ahead of the educated African? What are the relations between the teaching given to him and the views of the European community on his proper place in the social system?¹

Among the many problems of Africa there is none that has attracted more discussion, and indeed more controversy, than that of the type of education which should be given to the African. Much that has been written on the subject makes a valuable contribution to the body of informed thought of which every administration must take account in deciding policy; but it is also true that much that has been written, though admirable in its analysis of social factors and statement of principles, has failed to give that concrete guidance which the executive authority might have welcomed as to the manner in which the philosophy of education should be expressed in practice. Administrations have to translate abstract principles into the details of school courses, and the application of those principles is conditioned by financial resources, and by the quality of the teaching staff which can be made available.

Conceptions as to what is best in education are apt, moreover, to be coloured by political objectives; indeed, as will subsequently be seen, what at times has been put forward by administrations as a policy of education has in truth been only the expression of a political determination, or an effort to implement the view held of the place which the African should occupy in the social economy. Again, just as the policy of education is influenced by political considerations, so also is its practical application conditioned by financial limitations or by historical accidents which have affected the type of agency employed. It was asserted some years ago that nine-tenths of the education in Africa was in the hands of missionary bodies, and, whatever the accuracy of the figure,² it is

¹ For a recent discussion of these questions, see *Report of the Commission on Higher Education in East Africa*, Colonial 142, 1937, Introduction.

² As an example, Tanganyika calculates (1937) that of its one and a quarter million children of school-going age, roughly one million attend no school; 9,574 are on the rolls

clear that, in some territories at least, the administration has not in practice a full control of the application of the principles on which its educational policy is based. It will be seen that the French system is characterized by precision of objective and unity of method; but this is lacking in the British system, with its wide latitude in local practice, and, in addition, its large proportion of 'unaided' education over which the state assumes, in practice, little or no direction.

It would, therefore, seem advisable to give first some account of the course which education is taking in different territories, and of the policies followed. It will not be possible to give the facts in full detail, but an effort will be made to present sufficient data to explain the conditions which now determine educational policy in Africa. Tables giving such statistical material as is available will be found at the end of this chapter.¹

II. THE UNION OF SOUTH AFRICA

(a) *European Education*

The organization of the educational system of the Union owes its character to section 85 of the South Africa Act, which laid down that the responsibility for all but higher education was to rest with the provincial legislatures. Matriculation was taken as the dividing line, and this had the unfortunate result of preventing the retention of older boys in the secondary schools. The position has been further defined in the Financial Relations Act of 1913 and its amending Acts, under which provincial Education Departments receive subsidies from central funds, now calculated in the case of European education in proportion to the numbers of pupils in average attendance in each province. The details of this system have more than once been modified as the result of special inquiries, the most recent being that by the Provincial Finances Commission, 1934.² Industrial and vocational education, including trade and agricultural schools, have since 1924 ranked as higher education under Union control, though it is difficult to understand how their inclusion in the field of post-matriculation of government or native administration schools; 21,576 are on those of assisted mission schools; and 190,000 are said to attend unregistered mission schools.

¹ See Tables X and XI.

² *Report*, U.G. 46, 1934.

education can be justified. The principle of the subvention, which involves the separation of financial responsibility from administrative control, still remains a source of difficulty.

The Union Act leaves much room for overlapping in the administration of education, and the divorce of technical and industrial schools from other branches of secondary education is unusual. Nor have the local bodies yet received any effective share in the management of schools or the raising of finance. The Cape Education Ordinance, 1921, provides for local school boards, and there is a similar provision in the Transvaal and the Orange Free State, but not in Natal. Though the Cape school boards raised money under the old Cape Colony, their functions now, like those of the Transvaal and Orange Free State boards, are chiefly advisory.¹

Education is mainly provided out of public funds, though grants are made to private schools. It is free and compulsory up to the age of 16 in the Cape and the Orange Free State, up to 15 in Natal and the Transvaal. Secondary education is free in the Transvaal and partly in Natal, but not in the other provinces. Commercial and technical schools are Union institutions and fee paying.

(b) The University Institutions

There are in the Union four independent universities, and five university colleges which together form a fifth, the University of South Africa. They are largely dependent on the state for their finances. These institutions are impressive both in the scale of their buildings and extent of their resources, and it would be an interesting study, though one not possible to pursue here, to estimate the influence which they now exert on the life which South Africa is building up for itself. As in many of the more modern universities in Great Britain, a relatively high proportion of teaching is devoted to professional and vocational courses (including in the latter the course for the teaching diploma) rather than to general arts courses; this would appear to reflect a situation in which the demand for graduates with specialized training is greater than that for those with a general education. The excess of professional students over the numbers required in the Union itself is having its effect in the extension of the Union influence in other

¹ E. H. Brookes and others, *Coming of Age*, 1930, p. 416.

territories in which they find employment, such as Northern and Southern Rhodesia. That the influence of the Union university institutions has not been more marked in a direction in which many had hoped to see it develop—namely, the promotion of closer relations between the two white races in the Union—is due to the strength of the tradition of difference which exists among the population at large; but the association between students of the two races within those universities in which they meet on common ground is bound to have an increasing influence.

There is another direction in which it is important to mark their position. More than one observer has found that the universities have taken no inconsiderable part in producing the change which has been seen of recent years in the attitude of the Union towards native problems.¹ If there has not been a noticeable growth of sympathy towards native aspirations, there has been a keener interest in native life and a closer and more dispassionate study of native affairs. The development of systematic research into Bantu questions is significant. The University of Capetown, a pioneer in many fields, founded a School of African Life and Languages in 1918; a Chair of Bantu Languages was added in 1934. Stellenbosch has a Department of Bantu Studies with three teachers. Pretoria has lectures in anthropology and native administration, and the Witwatersrand has a well-staffed department including teachers of social anthropology, native law and administration, and languages.² In a number of university institutions there is a 'Bantu Studies Circle' founded under the influence of the National Union of South African Students; native questions are now increasingly discussed in students' debates.³ It is significant that this movement has continued in spite of the fact that government has ceased to make any contribution to the universities for Bantu studies, nor does it give students who have taken the course any preference in appointment to its administrative services. There is legally no colour bar in any South African university, and a certain number of non-European students have entered Capetown and Witwatersrand; but the difficulty which is to be encountered

¹ See M. Perham and L. Curtis, *The Protectorates of South Africa*, 1935, p. 75.

² See Chap. II, p. 53.

³ E. H. Brookes, *The Colour Problems of South Africa*, 1934, chap. vi.

by a Bantu native in gaining entrance is illustrated by the opposition which was at one time expressed to the appointment of a Zulu as language assistant in the Department of Bantu Studies at Witwatersrand.

(c) *The Two Official Languages*

European education in the Union is complicated by the recognition of two official languages, English and Afrikaans. In state schools the legislation of all the provinces, except Natal, lays down that primary instruction shall be given through the medium of the 'home language'; in disputed cases the decision of the school inspector is final.

After Standard IV parents may request that either or both languages be used as the medium of instruction. The second language is to be taught as a subject to all children unless their parents expressly object. The Natal law allows parents to choose the language of instruction of their children in all forms or standards, and provides that the second language may be taught as a subject if the parents request.¹ In all the provinces except Natal the majority of primary schools use Afrikaans as the medium of instruction; in Natal the Afrikaans-speaking pupils are a small minority. In the Union as a whole, however, the Afrikaans-speaking percentage of primary pupils was 57·8 in 1934. In 1934, of the secondary school pupils 18·7 per cent. were attending schools teaching in both languages, 47·1 per cent. schools with English as the medium, and 34·2 per cent. schools with Afrikaans. In the Orange Free State the greatest proportion of secondary pupils attend bilingual schools, elsewhere the majority are at English schools. In the case of higher education, the language of instruction has not been laid down by law, but the movement for the recognition of Afrikaans has had its effect in the development of the Universities of Stellenbosch and Pretoria as institutions which aim at making provision for the Afrikaans-speaking population. The incorporation of Pretoria (formerly the Transvaal University College) as a university in 1930 was the occasion for the assertion of its predominantly Dutch character, amid some protest from

¹ Ordinances 5 of 1921 (Cape), 13 of 1916 (Natal), 15 of 1930 (Orange Free State), 5 of 1911 (Transvaal).

those who had hoped that higher education might be a means of providing a meeting-ground between sections of the white population. The small University College of Potchefstroom, founded in 1866 by one of the Dutch Reformed Churches, was Dutch-speaking from its inception and is now Afrikaans-speaking.

(d) *The Finance and Control of Native Education*

Native education is under provincial control, but has been left largely in the hands of missions, subsidized by grants-in-aid. The allocation of funds for this purpose in 1855 was a direct result of the Constitution Ordinance granting representative government to the Cape.¹ The Royal Charter of Natal followed in 1856 by prescribing that an annual grant should be given for 'Native Purposes',² a portion of which was used for education. The state subsidy to schools for coloured and Indian children³ is based on the average attendance; native education is financed on a different principle, which has not failed to attract criticism as typical of the Union policy of racial differentiation. In effect, it places the liability for all expansion of educational services on the native population itself. This principle was first expressed in the Financial Relations Fourth Extension Act (5 of 1922), introduced soon after the Transvaal had passed an ordinance imposing a special tax on its native population. The provinces were debarred by the Act from imposing direct taxation on natives, and were required to expend on native education a sum not less than that which was actually being expended by them at the date of the passing of the Act. This was now provided from Union funds and was assessed at a total of £340,000; it was further provided that the improvement of native education might be subsidized by grants out of the revenues derived from native taxation, the basis of the subsidy being later defined in the Native Taxation and Development Act of 1925. This Act imposed a general tax of £1 on every adult male native, and a local tax of 10s. per hut on natives living in reserves. It created a Native Development Account,⁴ which is compiled in two portions, A and B. Into the 'B' account are paid the proceeds

¹ *Report of the Interdepartmental Committee on Native Education, 1935-6*, U.G. 29, 1936, p. 10.

² *Ibid.*, p. 19.

³ See Chap. VIII, p. 331.

⁴ See Chap. X, p. 555.

of the local taxes, and this section of the fund is used for local government purposes. Into 'A' account, from which expenditure on education is met, is paid the contribution of £340,000, and a proportion originally fixed at one-fifth, but subsequently fixed by Act 49 of 1935 at two-fifths of the general tax.

In assessing the merits of this system it seems sufficient to refer to the report of the Native Economic Commission of 1930-2.¹ 'It is not usual in treatises on Public Finance to consider taxation and public expenditure from the point of view of any one class of persons; the expenditure which the State considers necessary is regarded as a charge against the whole community, and it is the task of the Government to distribute this equitably among the various classes of persons which constitute the State.' Before the fund was created an advance of £223,644 was made to the provinces for native education, and this debt has constituted a heavy charge on it. It was calculated that the amount derived from the general tax would increase by 1·6 per cent. per annum with the estimated increase in the native population; but it is clear that, unless the facilities provided at the time of its inception were to be accepted as sufficient, even an income increasing in proportion to the population would not be adequate for necessary expansion. In fact, the revenue from the general tax has not increased in accordance with this estimate, partly because the number of taxpayers has not increased at the rate assumed, and partly owing to the failure to recover the full amount of tax in years of depression. In the years 1931-4 there was a steady decrease in the income of the fund, and the Native Affairs Commission in 1933² stated that so far as the fund had to meet the reasonable and accepted charges for native education it was bankrupt. In 1935-6 the fund would have shown a large deficit had not the government increased the contribution from the general tax to two-fifths for future years. The annual increase of income under this arrangement is calculated at 1 per cent.³ The total revenue of the fund in 1934-5 was £586,412, or less than one-eleventh of the money spent on European education, while the expenditure per head of native population (though

¹ *Report*, U.G. 22, 1932, para. 1058. See also Chap. XX, p. 1407.

² *Report*, U.G. 3, 1934, p. 13.

³ *Report*, op. cit., U.G. 29, 1936, p. 47.

higher than in any other British African territory save Zanzibar) was one-fortieth of that per head of European population. Under the new arrangement this proportion will be slightly altered in favour of the native population.

The fund is expended almost entirely in the form of grants-in-aid to schools under the control of missions. In Natal alone has provision been made on any considerable scale for government native schools; this development began in 1918, when the government took over some schools previously managed by the American Mission Board, and there are now eighty such schools under local committees which include representatives elected by parents, the committee being under the control of the Education Department. There has been no increase in the number of these government schools in Natal for many years, largely owing to their greater relative cost. The Transvaal and Cape have each one state native primary school under the European School Board of the district. The Cape has made provision for native education on a more generous scale than the other provinces; when the grant was fixed in 1922 its share, based on previous expenditure, was £240,000 out of the total sum of £340,000. Under its more liberal form of grant it has been found possible to give free primary education, whereas in the other provinces the schools charge fees of from 12s. to 15s. a year.¹

The general basis of the grant to schools is the payment of salaries of teachers; the practice in the payment of grants for furniture and equipment varies. While all provinces pay teachers' salaries in primary schools, in the secondary schools the Cape pays two-thirds of the salaries, while the other provinces meet the full cost. In 1934 the total number of state and state-aided schools was 3,133, of which 1,686 were in the Cape. The enrolment was 324,649, of whom girls slightly outnumbered boys, and the average attendance was 277,168. It appears that over 70 per cent. of the native population of school age are receiving no education. Of those who go to school 57 per cent. are in the sub-standards, only 2·4 per cent. in Standard VI, and less than 2 per cent. in secondary and higher institutions. The corresponding

¹ J. van der Poel, 'Native Education in South Africa', *Journal of the Royal African Society*, vol. xxxiv, no. cxxxvi, 1935, p. 322.

figures for the European population are 18 per cent. in the sub-standards, 10 per cent. in Standard VI, 16.5 per cent. in secondary and higher education. Of the total native population one in every 1,000 receives secondary and higher education; of the European, thirty in every 1,000.

In the mandated area of South-West Africa the administration pays the salaries of teachers and supplies the furniture and equipment in the mission schools, of which there were in 1936 thirteen for coloured children, with an enrolment of 801 pupils, seventy for natives, which were registered and eligible for government grants, and three for training native teachers. In the same year the total number of scholars in all schools, aided and unaided, was 5,723; state expenditure per head was 11s. 2d. The expenditure on coloured pupils was £8 19s. 3d. per head, and on European pupils, who numbered 5,723, £19 15s. 3d. per head.¹ Few non-European scholars proceed beyond the primary stage.

The position of missionary bodies in the Union is somewhat different from that which they occupy in other British territories. The control which the state assumes in return for its financial assistance is far-reaching: in particular, the payment of the salaries of teachers by the state tends to lead them to regard themselves as state servants.² There has been in the Union a wider divergence than elsewhere between the policy of government on native affairs and the views held by missionary bodies, and this tradition still influences the attitude of a considerable section of Europeans towards mission education. There have, even in modern times, been occasions when the official attitude towards missionary bodies has recalled something of the feeling which Dr. Philip provoked among settlers in the first half of the nineteenth century; a noteworthy instance of this occurred during the controversy on the colour-bar legislation in 1926. There is another point of importance. Native opinion is beginning to show itself impatient of missionary control, as is evidenced by the growth of the separatist churches. A list drawn up in 1932 comprises no less than 326 African separatist bodies.³

¹ See Table XI at end of chapter.

² J. H. Oldham and B. D. Gibson, *The Remaking of Man in Africa*, 1931, p. 123.

³ E. H. Brookes, *op. cit.*, Appendix II.

There are wide differences in the extent to which native parents are associated with the management of schools; some missions oppose the formation of local committees, while other denominations regularly establish advisory bodies representative of the native community. These are obligatory in government schools and are recommended for aided institutions in Natal; in the Cape they may be established under the Education Ordinance, with powers similar to those of a School Board; in the Free State they are a part of the machinery for amalgamated schools; and in the Transvaal they exist for 'rural community schools', but elsewhere are not officially recognized. The Interdepartmental Committee on Native Education,¹ while acknowledging that when first constituted an advisory body may cause extra labour, considered that, in view of the importance of creating a link between the school authority and the parents, local school committees should be established wherever possible.

The same committee strongly recommended that the control of native education should be transferred from the provinces to the Union Department of Education, and that the Native Affairs Commission, which at present allocates funds to the provinces for native education, should be eliminated. The proposal was that a new Department of Native Education should be set up under the Minister of Education, with a National Board of Native Education. It appears that this proposal was referred to the Natives' Representative Council at its first meeting in December 1937, but that the Council unanimously rejected the proposal.² The Interdepartmental Committee on Native Education also advocated the formation of a Native Education Fund to take the place of the Native Development Fund. The present system of block grants to the provinces was considered inelastic and incapable of expansion, and it was suggested that the state's contribution should be in the form of an annual *per caput* grant.³

(e) *Higher Education for Natives*

It may be taken that though entry to the universities is technically open to natives, it is in practice closed. Union policy has con-

¹ *Report*, op. cit., U.G. 29, 1936, p. 69; and R. F. A. Hoernlé, 'Native Education at the Cross-roads in South Africa', *Africa*, vol. xi, no. 4, 1938.

² *Manchester Guardian Weekly*, Jan. 28, 1938. ³ *Report*, op. cit., U.G. 29, 1936, p. 60.

centrated on the provision of higher education for natives at the South African Native College at Fort Hare, the creation of which was the direct result of a recommendation made by the South African Native Affairs Commission of 1903-5. Classes were first opened in 1916, and in 1923 it was incorporated under the Higher Education Act 30 of 1923, and as such receives from the Union the grant calculated on fee income which is available to other institutions of the same class. Fort Hare, however, only receives the portion of the grant based on fee income, whereas the other university institutions have a grant based on fees, endowments, and grants from local or other bodies. Fort Hare is also supported by the Transkeian Council and High Commission administrations. Its constitution declares its character to be that of a Christian college, though open to non-Christians. It prepares students for the degrees of the University of South Africa, an external examining body, and its courses are regulated by the requirements of these degrees; by 1936 over fifty students had obtained the B.A. degree, and last year two were presented for their B.Sc. The first woman graduated in 1928.

Great attention is given to Bantu studies, and of late years the college has opened classes in agriculture, maintaining a farm of 1,600 acres for this purpose; it has now become the centre of the Union scheme for educating native medical aids, which was made possible by the grant of £75,000 from the Witwatersrand Chamber of Mines. It is expected that this course will turn out ten graduates annually.¹ The total enrolment of students from 1916 to 1934 was 570. It was stated in 1934 that of past students 106 were ministers of religion, 139 teachers, 57 secretaries and clerks, 22 agricultural demonstrators, and 8 doctors. These last obtained their medical training abroad; seven of them are now practising in the reserves, the eighth among the native community on the Rand.

(f) *The Content of Native Education*

The teaching given by early missionaries was closely linked with their work of evangelization; as early as 1854, however, the cause of practical training was taken up by the Government of the Cape Colony under Sir George Grey, who in that year promised a

¹ See Chap. XVII, p. 1184.

subsidy to missions which would undertake to train native youth in industrial occupations. Institutions were subsequently formed at Healdtown, Lovedale, and elsewhere, but these were mainly devoted to the training of artisans; the ordinary school courses for long remained of a literary type, dominated by the examination standards of the European schools. A competent observer who began his career as a teacher in one of these schools has described the type of education as false and superficial.¹ The unsatisfactory nature of the instruction given added point to the arguments of those who opposed the extension of education to natives; they had some grounds for saying that education as then pursued seemed destined, in the words of Rhodes, to produce a nation of preachers and editors.

In truth, the controversy between those who held a 'humanist' view of native education, and their opponents, reflected something more than divergent conceptions of educational theory. To the one side, education of a European type symbolized the grant of equal opportunities to natives; the opposition of the other side reflected its view that the position of the native in the economic structure must always remain subordinate. The merits of the educational issue were obscured, on the latter side, by a display of self-interest, and on the former by a somewhat uncritical idealism. The controversy which was provoked by proposals to extend education to the working-classes in Great Britain turned equally on issues which had little reference to educational theory; and when the President of the Royal Society could urge in 1807 that the education of the labouring classes would be prejudicial to their morals and happiness,² his logic differed from that of the South African farmer mainly in the terms in which it was expressed.

In most countries of the world dispassionate study has only been given to the content of education when it has been accepted that it can no longer be confined to a special class, or directed to specialized ends, but must extend progressively to the whole population. That decision is one of general policy rather than of educational technique; once it is taken the major problem then

¹ E. W. Smith, *The Golden Stool*, 1930, p. 298.

² J. E. G. de Montmorency, *State Intervention in English Education*, 1902, pp. 222-3.

centres on the evolution of a suitable content for that range of education which can be given to the majority of the population with the greatest benefit to the social structure as a whole. In those conditions the educationist in his choice of method is increasingly controlled by the influence of outside opinion; education, in other words, becomes largely a co-operative effort. As regards the content of the more advanced or specialized stages of education, experience shows that its character and scope ultimately depend less on any educational theory than on needs connected with the positions which the products of such education will occupy, or the extent of the demand which society in its different activities makes for them. The educationist has to adjust his methods to these facts.

If something of the spirit which animated the older controversy is still seen in South Africa, the approach to the question has been modified by the tacit acceptance of the fact that education must in time be extended to the native population at large; the crucial question has become that of the type of education which should be given to it in the comparatively short period to which, for many years at all events, the school life of the majority of the Bantu population will be confined. As regards more advanced education, the type of opinion which would at one time have emphasized its radical unsuitability to Africans, now tends to concentrate on the efficacy of measures, such as territorial segregation or the colour-bar legislation, designed to confine the product of Fort Hare or similar institutions within the orbit of native life, and to prevent him from competing in the white economy. This change of attitude, for instance, seems to characterize the Dutch Reformed Church, which is taking an increasing part in educational activity. Attention is, in short, now directed less to finding reasons against the higher education of the native than to regulating the field in which he can make use of it.¹

Of the more formal examinations of policy which have been made in recent years, those conducted by the Native Economic Commission of 1930-2 and the Interdepartmental Committee on Native Education appointed in July 1935 are the most important. The former reflects a stage in the approach to native questions

¹ See speech of General Hertzog, *House of Assembly Debates*, vol. xxvii, 1936, c. 4086.

on which Union thought has already made some considerable advance. Assuming that there was little chance of a substantial increase in the funds for native education, the Economic Commission¹ confined itself to proposals which would turn the existing provision to better account. The recommendations made by the majority of its members showed a restricted vision of the scope of educational effort. Their view was that societies at the African level of development have educational needs which precede ordinary school education, involving, in particular, the conquest of beliefs in supernatural forces which are inimical to progress. 'Education', they write, 'must aim at transforming the native's whole outlook on life. The European bases his education on the three R's. But for the tribal native there is a great deal that precedes the three R's, and that is definitely more important than the three R's.'

The Interdepartmental Committee made a more comprehensive and a more informative approach to the problem. It included the heads of all the provincial Native Education Departments, and its report² may be taken as representing the view of the more progressive educational authorities of the Union. They recognized the essential connexion between the content of education and the environment of adult life. 'The education of the white child', they write, 'prepares him for life in a dominant society, and the education of the black child for a subordinate society.' In framing their views regarding the future of education they had to choose between the assumption that the political or social barriers imposed on the native would disappear, and the acceptance of the fact that the conception of segregation would continue to dominate policy. They thought that the honest course was to take the latter alternative. They nevertheless held that it is possible to raise the general educational level in a manner which is not incompatible with the frank recognition of the barriers to which they referred. Rejecting the suggestion that any advance can be made without an increase in literacy, they recommended that every native should receive at least an elementary education and that those who could benefit by further education should be

¹ *Report*, op. cit., U.G. 22, 1932, paras. 627-30

² *Report*, op. cit., U.G. 29, 1936, pp. 87-9, 106, 499.

enabled to proceed to it. They drew special attention to the short average school life of the native, roughly three years on a liberal calculation, and stressed the need for a curriculum which would be something more than a mere preparation for a further course which the vast majority would never undergo. In the case of the older pupils, they urged the need of substituting a course of teaching with a practical bearing which would be obvious to them, for the repetitive learning appropriate to young children. While recognizing the value of manual training for its own sake, they attached little importance to the teaching of local crafts which are becoming obsolete; they recommended, on the other hand, the development of agricultural training, and the training of women as itinerant teachers of child welfare and 'general home activities' on the lines of the Jeanes system.¹ These recommendations may have an important bearing on native education in the future.

It is noticeable that the Transkeian Territories General Council has taken particular interest in agricultural training. A farm was established at Tsolo in 1904, to which a school was attached in 1913, and a second was opened at Teko in 1921. In 1930 Pondoland instituted its own school at Flagstaff, which has now come under the United Transkeian Territories Council. In 1930 the Union Native Affairs Department started an agricultural school for the Ciskei at Fort Cox. These are institutions of some importance, well supported financially, and directed by European principals. They take students after passing Standard VI and give them a two-year course on the farms attached to the schools. Since 1916 a staff of native agricultural demonstrators recruited from the students at these schools has been gradually developed till in 1935 it numbered over 250. The services of the demonstrators have been sought as far afield as the Belgian Congo. There is some fear, however, that it may not be possible to keep up these schools; the demand for agricultural demonstrators is, for various reasons, already slackening, and shows signs of decreasing further.

A significant omission from the Interdepartmental Committee's Report is adult education, though many education officers realize its great importance.

¹ *Report*, op. cit., U.G. 29, 1936, paras. 556, 572. See below, p. 1228.

(g) The Linguistic Problem in Native Schools

As an interesting chapter of the report of the Interdepartmental Committee on Native Education of 1935-6¹ shows, the question of language is of unusual complication, not merely because there are within the Union seven recognized native languages,² with large multi-vernacular areas in some of the towns, but also because there are two European official languages. Up to about 1900 English had everywhere been given prominence at an early stage in mission schools, to the exclusion of the native languages; it is only of recent years that the value of a mother-tongue medium of instruction has been appreciated, or that regulations have prescribed a native language as a course of study.

The matter is still marked by a strong conflict of views. Educated native opinion resents anything which would prevent a maximum school period being devoted to learning English; it is a phenomenon seen equally in the coastal areas of West Africa, and was common in India before the 'nationalist' revival. There are also Europeans who ascribe the emphasis now laid on native languages to the unfortunate influence of the 'older anthropological school' which, in their view, plays into the hands of supporters of segregation by keeping alive tribalism.³ The official regulations, accepted with reluctance by some missionary bodies, now prescribe that the language of instruction shall be the mother tongue, in Natal for six years, in the Cape and Free State for four, and in the Transvaal for two. Thereafter an official language is to be introduced as the medium as rapidly as possible. In practice, the official language used as a medium is almost everywhere English. In all primary schools a native language must be taken as a subject, though in the Free State and Transvaal Afrikaans may be substituted by pupils whose mother tongue it is. In all the provinces one of the two official languages must be taught in all classes, though only orally in the first year. In the Free State the other official language is usually also taught, so that a pupil who proceeds through the primary school is for four or five years of the course taught three languages.

³ See Chap. III, p. 81.

III. SOUTHERN RHODESIA

(a) The European Schools

Generous provision for European education has been a prominent feature of Southern Rhodesian policy since the first Education Ordinance of 1899, when grants on a £ for £ basis were made to the schools then conducted by missions. On the recommendation of a committee appointed in 1908, government assumed the direct control of all primary education and established the first state secondary school. Six of the seven original aided mission schools are still in existence; the additional schools established by government since it took up the responsibility for European education numbered seventy in 1935; seven of these, and five of the mission schools, give education classed as secondary. In order to provide facilities in the outlying areas, grants are made to 'farm schools' in country districts, in which the parents supply the buildings and furniture while government provides the teacher's salary and equipment. In 1934 there were sixty-three such schools. In 1935 the government sought to encourage the attendance of rural pupils at more efficiently organized schools by the provision of hostels for boarders; this led to a reduction in the number of farm schools to forty-six. A technical school at Bulawayo, founded in 1927, offers a five-year course for boys who aim at acquiring professional qualifications, though the majority leave the school for private employment at the end of the third year of the course. In 1936 there were 198 pupils enrolled in this institution, and 10,532 in all European schools. Primary education was made free and compulsory in 1931. Since 1935 secondary pupils pay no tuition fees, and a 10 per cent. rebate is given on boarding fees if paid before a specified date. The gross expenditure on European education in 1936 was £323,179 and the cost per pupil £30 13s. 9d. This high cost is due not only to the provision of free education but to the large proportion of pupils who are of necessity boarders.

The territory is, in addition, exceptionally favoured in the matter of endowments. The Beit Bequest offers annually for competition seventy-two scholarships of £27 per annum each, of which forty-two are tenable in primary and thirty in secondary schools. It also awards each year thirteen bursaries of £100-£60 per annum,

and three engineering scholarships of £150 per annum, tenable at South African universities, and three engineering fellowships of £375 per annum for students taking post-graduate courses overseas. Three of the Rhodes Scholarships of £400 per annum tenable at Oxford are earmarked for Southern Rhodesia.

From the first, European education in Southern Rhodesia has been closely linked with the Union system. Many teachers have been trained in the Union, and at an early stage schools adopted the standards of the Cape. Secondary education has up to now culminated in the Matriculation Examination of the South African Joint Board. This policy was endorsed by the Education Commission of 1929,¹ but during 1936 Southern Rhodesia struck out a new line for itself. An officer of the Board of Education in the United Kingdom had been invited to investigate European education in Southern Rhodesia, and his report was presented in 1936.² As a result of this report important changes have been made: education affairs can now be dealt with by the Governor in Council instead of by vote in the legislative assembly; the inspectorate is now (through the Chief Inspector) directly responsible to the Minister and not to the Director of Education. One of H.M. Inspectors of Schools from the Board of Education has been appointed Chief Inspector for two years, and so seriously is the matter viewed that the Prime Minister has himself taken over the Education portfolio. In October 1937 he made a speech to the House indicating the policy it was now proposed to follow, which would later be embodied in an Education Act.

Primary education, clearly divided from secondary education, is to be provided up to the age of 12 years, and to be free from a departmentally imposed syllabus. The school-leaving age is to be raised to 16 years, and when the child is 12, parents will have a choice of three types of secondary education: modern, academic, and technical, the first course being free from all external examination. In academic schools the practice has been to take the South African Matriculation in Form V. This is to be abolished and the Cambridge School Certificate is to be taken a year earlier, the Form V year being devoted to post-certificate work.

¹ *Report*, C.S.R. 27, 1929, pp. 106 ff.

² Southern Rhodesia, *Report of the Education Commissioner*, C.S.R. 25, 1936.

One of the more important ideas underlying these proposals is to give effect to a policy advocated in the Hadow Report on the Education of the Adolescent:

'that all the children of the country who do not go forward to "secondary education" in the present and narrow sense of the word, should go forward none the less to what is, in our view, a form of secondary education, in the inner and broader sense of the word, and after spending the first years of their school life in a primary school should spend the last three or four years in a well equipped and well staffed modern school under the stimulus of practical work and realistic studies, and yet, at the same time, in the free and broad air of a general and humane education'.¹

It is contended that secondary education has hitherto been academic and admittedly unsuited to the majority of children.

In Southern Rhodesia grants-in-aid to schools for the education of coloured children were first made in 1903. In 1916 two government primary schools were established for this purpose. There are now thirteen schools for coloured and Indian children, of which eleven are maintained by government; the total enrolment in 1936 was 1,135 and the total government expenditure £11,409.

(b) *Native Education*

Southern Rhodesia shares with the Union the system under which the majority of native schools are provided by the missions. Grants are made on a *per caput* basis, increasing in accordance with the standard of the school. In addition, government pays part of the salaries of teachers and contributes towards special courses for the training of native teachers and towards the production of vernacular publications. Such grants in 1935 totalled £52,926, while the pupils enrolled in aided schools numbered 105,466; of these 49,999 were girls. The disproportion in the cost to government of native and European education is greater than in the Union, the figures being £30 13s. 9d. for each European and 13s. 9d. for each native pupil. Government is directly responsible for two schools founded in 1920 and 1921 at Domboshawa and Tjolutjo with the specific aim of giving a training in crafts,

¹ Quoted in Southern Rhodesia, *Report*, op. cit., C.S.R. 25, 1936, p. 16.

which can be turned to account in the improvement of conditions in the reserves, though this is accompanied by the proviso that natives must not be trained in such a way as to enter into competition with Europeans. These schools have become the pivot of a policy adopted in 1929, which emphasizes the principle that school instruction must rank as only one of many agencies directed towards the betterment of native life. In that year native education became the function of a Department of Native Development, with an Education Officer as Director, advised by a board representative of the Native Affairs Department, the European and Native Education Departments, the Medical and Agricultural Departments, the Native Land Board, the missions, native welfare societies, and the general public. In 1935 a change was made, and all departments connected with native administration and development were placed under the Secretary for Native Affairs, who is also Chief Native Commissioner and Director of Native Development. The Education Officer became Director of Native Education instead of Director of Native Development. To many the change has been welcome on the ground that it makes for efficiency by reducing departmentalism; others have felt that native education has lost in independence.

The original view held of the purpose of native education is shown in the definition of a first-class school in the Education Ordinance of 1903 as one in which 'pupils are taught industrial work, receive a sufficient knowledge of the English language, and are trained in habits of discipline and cleanliness'. Some measure of the more extended view now taken is afforded by the fact that the late Director of Native Development, Mr. H. Jowitt,¹ defined its aims as 'the effective organization of the African's experiences so that his tendencies and powers may develop in a manner satisfactory to himself and to the community in which he lives'. It has been sought to give practical expression to this conception, not only in the course of training for school teachers, but in the development of instruction to adults by means of demonstration in improved methods of house building, village planning, and agriculture. The majority of these demonstrators are trained at Domboshawa. Particular importance has been attached to the

¹ *The Principles of Education for African Teachers*, 1932, p. 48.

training of agricultural demonstrators in view of the necessity for a rapid improvement in methods of cultivation in the reserves. After a three-year course in agriculture these men are sent to the reserves; whereas in the Union and Kenya the work of the demonstrator is mainly instructional, in Southern Rhodesia he is expected to convey lessons of better cultivation by personal cultivation, while his advice is at the same time at the disposal of his neighbours. In 1935 there were fifty agricultural demonstrators with 1,722 plots, an increase of 28 per cent. over the 1932 figure.

Another aspect of this broad educational policy was the adoption in 1929 of the recommendation of the Phelps-Stokes Commission¹ regarding the establishment of Jeanes schools in Africa. This type of school had its origin in a bequest by Miss Anna T. Jeanes for the training of visiting teachers for negro schools in America. The Jeanes teacher is given charge of a group of schools, and is expected to stay at each centre for some days and assist the village schoolmaster in his work and give friendly advice. One aim of the system is to fit the bush school into local community life by providing interesting teaching which is in close relation to local needs.² A Jeanes course for men at Domboshawa gave instruction in 'community welfare work' based on the special needs of the area, as well as in school subjects and in the art of teaching. The students were as a rule married men, who came from mission schools and had previous experience of teaching; they were nominated by missions to which they returned on completion of their training, and during the course their wives received instruction in maternity and child-welfare work. Training at Domboshawa was suspended in 1935; it was considered that sufficient men had been trained and that, although the men chosen for the course were the best the missions could offer at that time, the teachers who were leaving the ordinary training courses had a better knowledge of teaching than many of the Jeanes teachers. Girls are trained in a Jeanes school at Hope Fountain, a station of the London Missionary Society, as 'home

¹ *Education in East Africa* (ed. T. Jesse Jones), 1925.

² Further mention of Jeanes training is made in connexion with Jeanes schools elsewhere; see below, pp. 1252-3.

demonstrators'; the course is similar to that formerly given to the wives of Jeanes teachers.

An experimental course for the training of native chiefs was started at Domboshawa in 1936.¹

IV. BRITISH COLONIAL AREAS

(a) *Education Policy*

In education, as in the other social services, each British dependency has its own local department, which retains a large measure of initiative and control over policy and administration. The British Government has, however, announced certain principles of general application for the guidance of colonial governments in educational matters. These principles have been adopted by successive Secretaries of State upon the advice of the Advisory Committee on Education in the Colonies, which was set up in 1924, at first with the title Advisory Committee on Native Education in the Tropical African Dependencies.²

The first of these declarations of policy was made in 1925.³ The central problem was considered to be the finding of ways to improve what is sound in indigenous tradition. 'Education should be adapted', said the white paper, 'to the mentality, aptitudes, occupations and traditions of the various peoples, conserving as far as possible all sound and healthy elements in the fabric of their social life.' Education was to raise up leaders from among the people, as well as to assist the peasantry towards better standards of life. The greatest importance was to be attached to religious teaching and moral instruction. The most effective method of training character was considered to be the residential school. The importance of women's education was recognized, but great stress was laid upon the dangers which might attend any action in this matter, which did not take the fullest account of the subtle social reactions which would probably follow.

At that time education in the African dependencies, with the

¹ *Race Relations*, vol. iv, no. 1, 1937, p. 24.

² See Chap. VI, p. 161.

³ *Education Policy in British Tropical Africa*, Cmd. 2374, 1925. In 1847, however, the Privy Council Office communicated to the Colonial Office a considered statement (Colonial Office Library, *Miscellaneous Pamphlets*, vol. i, no. 1) on educational policy for the coloured races. See H. S. Scott, 'The Development of the Education of the African in Relation to Western Contact', *The Year Book of Education*, 1938, pp. 707-11.

notable exception of Northern Nigeria, was still mainly in the hands of various missionary bodies, and the government Education Departments were at an early stage of their development. The British Government announced¹ that it welcomed and would encourage all voluntary educational effort which conformed to its general policy, but it reserved to itself the direction of educational policy and the supervision of all educational institutions, by inspection and other means. It was recommended that in all the dependencies advisory boards for education, both central and provincial, should be set up. These advisory boards should include representatives of the Medical, Agricultural, and Public Works Departments, together with missionaries, traders, settlers, and representatives of native opinion.

It was essential at the same time to announce some decision upon the conflicting opinions then being canvassed, on the issue whether the governments should conduct their own schools, or whether they should, on the other hand, leave the management of the schools to the missionary bodies, and limit the activities of the Education Departments to the functions of assistance, advice, and supervision. The statement of policy took up a position which lay plainly half-way between the rival opinions. Provided that the required standard of educational efficiency was reached, aided schools were to have a place as important as that of the schools conducted by the governments themselves.

The next statement of policy related to the place of the vernacular in native education.² It was recognized 'that vernaculars must be used in the first stages of elementary education'. Encouragement was given to the displacement of vernaculars, spoken by limited numbers, by dominant or union languages.³ English was, however, regarded as a necessity in all intermediate, secondary, and technical schools, and 'if it is a necessity in these, its inculcation must commence in the higher standards of the elementary schools'. This language policy has been endorsed by the resolution of the Council of the International Institute of African Languages and Cultures.⁴

³ See Chap. III, pp. 68-9, 88-9, 91-2.

⁴ J. H. Oldham and B. D. Gibson, *op. cit.*, Appendix A.

In a *Memorandum on Native Policy in East Africa* issued in 1930¹ the British Government declared that its objectives included 'the spread of education in the widest sense'. Such education was to be made available for adults as well as for children and youths, and was to aim not merely at inculcating efficiency in clerical duties or handicrafts, but at raising the standard of knowledge and intelligence of the whole community, with a view to effecting a transformation in the daily lives of the people.

The continued study of the subject by the Advisory Committee led to increasing stress being laid upon the importance of bringing education into the closest relationship with all the other agencies of social improvement. The emphasis which had from the first been laid upon the necessity for educating the whole community, not only its children, was maintained and fortified by the working out of methods by which this might be undertaken.² It was realized, too, that the extreme caution which had been recommended in the matter of women's education had, perhaps, been over-stressed. In any case, the decade following the white paper of 1925 witnessed a number of experiments in the education of girls which demonstrated that, even in Moslem areas such as Zanzibar and Northern Nigeria, a bold policy could be justified. The Commission on Closer Union in East Africa³ advised a less cautious line. Yet education in the dependencies, together with the other social services, has been weighted strongly in favour of the male part of the population. Dr. Mary Blacklock⁴ published a report on this matter in 1936, and put forward the view that a dangerous disequilibrium was being allowed to develop between the care of the men and the neglect of the women. This view was endorsed by the Advisory Committee and accepted by the Secretary of State, who distributed Dr. Blacklock's report to all colonial governments for their consideration and guidance.

No separate statement of policy relating to secondary and university education has been published; but the Committee has

¹ Cmd. 3573, 1930.

⁴ 'Certain Aspects of the Welfare of Women and Children in the Colonies', *Annals of Tropical Medicine and Parasitology*, vol. xxx, no. 2, 1936, pp. 221-64.

drawn attention¹ to the increasing demand of the African for higher education, which tends to be met at present, by those who can afford it, by study at European or American universities. It is pointed out that the resultant efflux is socially and intellectually undesirable, and that the courses provided at these institutions are unsuitable to African conditions. Another unfortunate result of this situation is the orientation of a great deal of school education towards the curricula required by European examining institutions. The committee recommended, therefore, that plans be made for the development in Africa of selected institutions of university standard, having regard in their curriculum to the needs of the African environment; in the interests of economy such institutions should, so far as possible, serve several territories. It was admitted that they must in the initial stages be dependent upon some English university, and the committee suggested that London University should be asked to modify its requirements to suit the needs of Africa.

It appears that the publication of these recommendations was postponed pending the report of the commission which was appointed in 1936 to consider the question of higher education in East Africa. Part III of that report² deals with 'Advanced Education', and is understood to have been accepted by the Secretary of State on the advice of the Advisory Committee. It may, therefore, be regarded as a statement of policy on advanced education in East Africa, and the general principles which it formulates are clearly of wider application. The Commission viewed as inevitable and desirable the development of institutions in Africa of university rank, though they pointed out the dangers of a too hasty advance. They did not hesitate at the financial implications of such a policy. The report shows them to have considered carefully the claims of primary, secondary, and post-secondary education upon the limited funds available, and to have decided that the great expense of university-type education, though it may sometimes appear disproportionate, should be worth while even in the interests of primary education. Money spent on higher education would return to primary education in the form of

¹ A.C.E.C. 44/33, A.C.E.C. 24/35, A.C.E.C. 7/36 (unpublished).

² *Report*, op. cit., Colonial 142, 1937.

teachers, to health in the form of doctors, to economic production in the form of agricultural, veterinary, and forest officers. Advanced education is, therefore, to be of a definitely utilitarian type; it is, however, stressed that a technician, to be successful in his profession, needs wide culture and a strong character, and the secondary schools and post-secondary colleges must endeavour to supply these needs.

It may be convenient here to refer to Part II of the Commission's report, which concerns primary and secondary education. Its recommendations endorse the lines of earlier policy, but there are important differences of emphasis. The Commission agree that governments should continue to work through the missions, but urge the need for closer inspection and control and for a drastic improvement of primary education. They also point out that missions have little prospect of expanding financially, and that practically all new developments must, therefore, come from government resources. In particular, new government secondary schools should be established. They stress the vital need for further education of women and girls and for the development of adult education. The report of the Commission has a special significance both in its optimistic view of African capabilities and in its belief that over-caution may have as many disadvantages as over-rapidity.

(b) Education Administration

The declaration of a guiding policy for all the dependencies has not produced strict uniformity in the manner in which colonial governments have interpreted that policy. Local circumstances varied greatly at the time when it was declared, and the local developments since 1925 have varied correspondingly. Where the missions had already covered most of the country with a network of schools—as in Uganda and Nyasaland—the governments have worked almost entirely by assisting and guiding the missions. Where the most suitable channel through which to direct education was found to be the native authorities—as in Northern Nigeria and the Lake Province of Tanganyika—native administration schools have become the basis of educational policy. In other circumstances, as for instance in Zanzibar and on the

Tanganyika coast, schools conducted directly by the government are a predominating element in the school system.

The healthiness of a system which allows such adaptations to local needs cannot be questioned; but the very existence of this variety in the types of school creates a special need for an agreed nomenclature, applying to all the dependencies, so that such terms as 'elementary', 'primary', 'intermediate school', 'central school', 'junior secondary', 'college', 'trade school', and 'technical school' may have some constancy of meaning.¹ Confusion is caused by the use of these terms in different senses in almost every territory. Worse than that, the lack of precision in nomenclature has tended to the application of high-sounding titles to schools whose performance does not justify their names. This, in Africa, has had regrettable results. A boy who has completed his course at a so-called 'college' may face bitter disillusionment if he attempts to assert himself in competition with the product of an overseas college. An African who has attended a so-called 'technical school' to be trained as an 'engineer' cannot be expected easily to reconcile himself to the fact that he is employable only as a mechanic's mate or a road ganger. When schools which, in fact, do little more than teach reading and writing are represented to be secondary schools, there results a tendency to cram the curriculum in the top classes with subjects which the children cannot assimilate, in order to justify the unjustifiable name, and not only is the process of creating genuine secondary courses rendered difficult, but the secondary course, if set up, tends itself to be 'overgraded' as a 'college' course. In this chapter the first six years of normal school life will be spoken of as 'primary', and the seventh to twelfth years as 'secondary', following the recommendation of the East African Commission of 1936-7.

In spite of all the local adaptations, however, some progress is being made in pursuing certain common objectives. There has in recent years been an increasing effort to relate education as closely as possible to the needs of African communities.

The criticisms levied against the system followed in the British colonies are numerous; they include the domination of British school examinations, the neglect of girls' education, and the

¹ *Report*, op. cit., Colonial 142, 1937, p. 35.

bookishness of some of the schools; but it can at least be said that these defects are now fully recognized. The main burden of criticism to-day is against the quantity quite as much as against the quality of the schools. It has been pointed out, for instance, that at the present rate of expansion in the Gold Coast, assuming that the number of children of school age remains as at present, universal education will not be achieved for 600 years. Such calculations are important and serious, but the premisses on which they are founded are open to question. The expansion of education ought to take place by geometrical progression; teachers train not only literate peasants, but more teachers, and not only teachers, but other social workers. In the present stage of development colonial education is—or at any rate ought to be—creating means of training teachers in large numbers which, in another decade or two, will make possible a much more rapid expansion of the school system. To extend the primary schools too widely, before the advanced institutions for training teachers and other African social workers are yet in working order, might not be the quickest way to universal education.

(c) *The Missionary Schools*

Although the original inspiration for missionary work was, no doubt, the desire to make converts, there was not lacking a broader purpose. This is best expressed in a well-known passage in Livingstone's journal: 'In the glow of love which Christianity inspires, I resolved to devote my life to the alleviation of human misery.'¹ There have, it is true, been certain bodies with whom the impulse to effect conversions has seemed to outweigh all other considerations; but it would be far from true to say that this spirit has been characteristic of missionary endeavour as a whole. The missionary in Africa came at an early stage under the influence of the fact that he was often the sole agent of civilization; his activity was, by the force of circumstances, extended over almost every field in which the deficiencies of native life appealed for his assistance. The increasing measure of state control envisaged by the Colonial Office memorandum of 1925 might have been unacceptable to the Protestant missions, had it not given a prominent place

¹ *Missionary Travels and Researches in South Africa*, 1857, p. 5.

to the formula that native education must be 'based on religion'. That formula, however, enabled the conference of missionary bodies on African problems, which met at Le Zoute in 1926, to extend a welcome to the policy laid down. In an important resolution¹ it accepted the fact that education is the proper function of government, but expressed the view that, as the education of natives could be of no value without religion, it should be left to a large extent in the hands of missionaries, aided by government subsidy and organized under government direction. The chief sphere of mission activity must lie in the field of primary and secondary education; higher and technical instruction should ordinarily be conducted by government through the agency of governing bodies on which missionaries are represented, though this should not prevent missions from conducting higher institutions, provided they conform to conditions laid down by government. The views of the conference regarding the use of native languages in education were in the main the same as that embodied in the Colonial Office memorandum of 1927.²

The Roman Catholic missionary societies have welcomed government assistance and supervision in their schools, but they have great difficulty in accepting any arrangements which might result in Roman Catholic scholars attending institutions not under the control of the Roman Catholic Church. Their position is, therefore, that they cannot regard a government or native administration school as a suitable one for their adherents to attend.³ In regard to the grant by governments of financial assistance to mission schools, the policy commended to colonial governments, on the advice of the Advisory Committee, is that grants should be given 'only to institutions that are managed and taught by the right kind of person', and that the utmost possible freedom should then be given to such teachers and managers.⁴ The statement of policy is so expressed as to make it plain to voluntary bodies that they can only expect government aid if their school staffs are as well qualified for educational work as the members of the government education service.⁵ Subject to this

¹ See E. W. Smith, *The Christian Mission in Africa*, 1926, p. 110.

² See above, p. 1230.

³ *The Catholic Times*, Oct. 15, 1937.

⁴ *Advisory Committee on Education in the Colonies, Memorandum on Educational Grants-in-Aid*, April 1933, Colonial 84, p. 5.

⁵ *Ibid.*, p. 6.

proviso, it is recognized that the expenditure on staff should be the basis upon which the governments calculate their grants in aid of mission schools.¹ This policy, however, immediately encounters the difficulty, that mission teachers rarely expect to be paid the full salaries which they could command if they were not giving their services from other motives. This difficulty, it is suggested, can be overcome if the government assumes, for the purpose of the grant, that the missionary body is paying a certain salary for a certain type of qualified teacher. If, then, the mission and the teacher agree on a lower salary, the balance of the grant may be used by the mission for other educational expenditure. The Commission on Education in East Africa expressed itself as extremely doubtful about the wisdom of this provision.² It has not, in practice, proved possible to enforce the provision that mission staffs must possess qualifications equal to those of the government education service. As standards rise, however, this question of securing adequately qualified staff in mission schools is becoming increasingly difficult: it may be expected to present the governments with complex administrative problems, and even more to impose a great strain upon the resources of the missions in money and in personnel.

The administrations exercise control over mission schools chiefly through inspection, and through regulations regarding the opening and closing of schools. It is clear that in most territories the inspectorate is at present quite inadequate for this purpose. Tanganyika, for example, has now an authorized establishment of six inspectors of education, but shortness of staff prevents the inspection of a number of assisted mission schools.³ Elsewhere there is evidence that schools, if inspected, are seen at very irregular intervals.

In most territories teachers in all assisted schools have to be registered, and a definite procedure is laid down which must be followed before a school is opened. In Southern Nigeria it has to be shown that a suitable person has been appointed as manager, that the teachers have the minimum qualifications and are registered, and that the land is occupied under title or with the consent of

¹ *Ibid.*, p. 10.

² *Report*, op. cit., Colonial 142, 1937, p. 37.

³ *Report to the League of Nations on Tanganyika Territory*, 1937, p. 122.

the local community. In Northern Rhodesia permission is obtained from the district authorities, who must consult the native authorities. In most territories, also, schools may be closed on the advice of the Advisory Council or a similar body, if they contravene the regulations regarding registration of teachers or the like; in Kenya they may be closed if they are held to be detrimental to the physical, moral, or mental welfare of the pupils. Kenya and Southern Nigeria add to these provisions the important rule that all schools, whether assisted or non-assisted, shall be open for inspection at all times, a penalty being prescribed for refusal. In Tanganyika, where the propriety of the use of rules regulating the opening of schools for the purpose of 'zoning' areas between different missions has been the subject of debate, schools giving religious instruction only have now been exempted from control. While administrative limitations on the areas within which missions operate may present difficulties, there seems ground for control in some districts, in order to discourage an activity on the part of some missionary bodies which resembles rather the process of pegging out claims in a mining area than a genuine extension of educational effort. It may be added that there is not in the British arcas any discrimination between 'national' and 'foreign' missions, nor between missions of different denominations.

An important step in the co-ordination of activity has been taken in the association of official and missionary representatives in the local education boards or advisory councils which now take a large share in regulating educational matters. The institution of such bodies was an essential part of the recommendations of the Advisory Committee in 1925, and effect has been given to it in all territories. In Kenya separate councils have been constituted in connexion with the education of the four groups—European, Indian, Arab, and African. In Tanganyika, Uganda, Nyasaland, the Gold Coast, Sierra Leone, Nigeria, and the Gambia, Africans are now represented on the advisory bodies concerned with African education. The constitution of the Advisory Committee for Tanganyika may be quoted as typical. It includes the Director of Education as chairman, the Director of Medical and Sanitary Services, eight nominated representatives of missions, two of the Chamber of Commerce and Planters' Association, and two

Africans. In Northern Rhodesia and Kenya unofficial members of the legislative council are included in the advisory bodies. In some of the territories the Central Committee or Board of Education is supplemented by local committees; in Tanganyika and in Southern Nigeria, for instance, there are provincial committees; in other areas, such as Kenya and Uganda, there are district boards or committees. They advise regarding the management of elementary schools and the allocation of grants-in-aid; their members include representatives of the native authorities of the district. In Bechuanaland each tribal reserve has its local committee; an interesting result of the establishment of these committees was that the natives voluntarily offered to raise a levy for school purposes.

In Northern Rhodesia a few school committees consisting entirely of natives have been set up in the Northern Province, and in connexion with the government school at Ndola. In 1934 an Education Board which includes representatives of the paramount chief and his Kgotla was created for the Barotse Province. These Rhodesian committees are at present responsible for school attendance and the maintenance of buildings; it is hoped later to give them some financial powers, but there has been a good deal of opposition to the movement from missionaries, and it is not widely developed.

(d) Native Interest in Education

There is evidence in almost every area of a desire on the part of natives for increased educational facilities. The native authorities participate in educational work in some cases by raising special funds, in others by maintaining their own schools. The tribal levy raised in 1898 to found the Lerothodi Technical School in Basutoland produced over £4,000. Here there is an education levy of 3s. per taxpayer. In Bechuanaland tribal levies, imposed by request of the natives themselves, are in force in eight of the tribal areas. In Swaziland the native authority has taken a large share in creating the school at Matapa, which takes the place of the school founded by the Swazi rulers at Zombode. In Nyasaland the interest of native authorities in education has taken the form of requests that it be made compulsory, and in 1935 the Henga-Nkamanga

Native Administration passed rules to that effect for five villages within its jurisdiction. As a result the average attendance increased in each of these villages, that of girls being more than doubled in four of them. The teaching staff was also doubled. Other native authorities have asked for information regarding the progress of the experiment, though its extension to other areas would have to face less favourable conditions. In Uganda the native authorities of Bunyoro and Toro impose a special education tax of 1s. per head;¹ the Buganda Council was willing to impose rates, but this was considered undesirable on the ground that existing taxation was sufficiently high. In 1935 the moneys raised from native administration funds and education rates, to supplement those from the central government, amounted to £21,236, which was allocated through the district boards.

It is stated of the Local Native Councils of Kavirondo and Kikuyu, in Kenya, that they are more willing to raise the local rates for education than for any other purpose; the total sum voted by such councils in Kenya for education since their inception in 1925 to the end of 1934 was £92,414. In Kenya the Local Native Councils have been allowed to erect schools and provide boarding expenses of pupils, but the control and management of the schools are in the hands of the government. These schools are not to be confused with the independent schools which have sprung up in the Kikuyu reserve as a result of differences of opinion between the native community and certain missionary bodies. The existence of these independent schools, which are found in several territories beside Kenya, is of some significance. They are evidence that Africans may in certain circumstances not be content to allow those who control education to use the schools for purposes of which a large body of African opinion does not approve; and they constitute a warning that educationists in Africa may greatly increase their own difficulties, if they do not find means for associating African opinion with them.

In Tanganyika, in 1936, thirty-six of the seventy-four village schools financed entirely from public money were classed as native administration schools.² The present policy is to hand over the

¹ See Chap. X, p. 576.

² See *Report*, op. cit., Colonial 142, 1937, p. 40.

remaining government village schools to the native administrations wherever possible, and from the beginning of 1938 this is being done, except in the case of some schools in towns where no traditional authority exists. The buildings, furniture, and the maintenance of boarders are financed by the native administration, but the educational direction is under the supervision of the government. Teachers' salaries have been paid by government, but, following a policy of increasing gradually the responsibilities of native authorities, it is proposed to make a grant from central government funds to the native treasuries, to enable these salaries to be paid by the local authorities. In the case of the large government primary school at Moshi, a committee of local elders visits the school and offers advice.

By 1936 there were fifty-eight native administration schools in the Southern Provinces of Nigeria and the Cameroons, with 3,684 pupils, towards the maintenance of which the native treasuries contributed over £9,000 in 1936. In some areas the school management is in the hands of a committee, usually presided over by the District Officer. The Education Officer, where there is one, is a member, and in most places the committee includes representatives of the missions; the voting of funds is in the hands of the native administration, acting upon the advice of the District Officer. In other areas the native authority practically assumes all the duties of a manager. In the Northern Provinces of Nigeria the result of the restricted activities of missions in Moslem areas has been, that government has relied largely on the native administrations for the development of education, and the native treasuries bear the entire capital and recurrent cost of all elementary, middle, and girls' schools, with the exception of two government schools. In 1936 this cost was estimated at £44,467.

In the Northern Territories of the Gold Coast the introduction of indirect rule was accompanied by the policy of transferring to native administrations the responsibility for existing government schools.¹ One native authority took over this responsibility in 1935, and further transfers, with the establishment of new native administration schools, are expected shortly.

¹ See Chap. IX, p. 476.

(e) *Extent of Secondary Education*

Of the children now at school the great majority are in the primary stage, and a great proportion have a very short period of school life. It is, indeed, doubtful whether the figures supplied by administrations do not include considerable numbers, such as pupils in a certain class of mission 'bush' school, who cannot properly be said to be in receipt of any form of secular education, however that term be defined. It is noteworthy that Tanganyika has lately found it desirable to exclude from registration all evangelistic schools and catechetical centres.¹ It is no disparagement of the value of the work accomplished by missionary effort to say that this is one of the inevitable results of a system which leaves so much of the initiative in education to the missionary bodies. 'Few things', as was observed by the authors of *The Remaking of Man in Africa*,² 'make a stronger appeal to the imagination than the awakening desire for knowledge which finds expression in the tens of thousands of little village schools that are to be found throughout the length and breadth of the continent.' It is, in truth, the desire for school teaching rather than any doubts about his own faith which is often the inducement for the native to bring his children to the missionary. There are some bodies which are content to meet that desire with a smattering of religious teaching imparted by ill-trained native teachers, who are often paid at rates so low that they have to be supplemented by the cultivation and marketing of cash crops, operations which can be done only during 'school hours'.³ There are, however, many missionary bodies which would wish to combine a more effective type of education with their religious teaching, did their resources permit.

The diversity of practice and nomenclature makes it difficult to distinguish the primary from the secondary stage of school education. Secondary education can be obtained at four institutions in the Bechuanaland Protectorate. Swaziland and Basutoland have each 1 school classified as secondary, the Gold Coast 3, the Gambia 4, Sierra Leone 9, Northern Nigeria 12, and Southern Nigeria 30.

The East African Education Commission of 1937 briefly reviewed

¹ *Report to the League of Nations on Tanganyika Territory*, 1937, p. 120.

² J. H. Oldham and B. D. Gibson, *op. cit.*, p. 63.

³ *Report*, *op. cit.*, Colonial 142, 1937, p. 45.

in its report the existing state of secondary education in the territories covered by its term of reference. There were no facilities for the secondary education of girls in Kenya, Tanganyika, Zanzibar, Nyasaland, Northern Rhodesia, or Uganda. For boys, Kenya had as yet no schools of full secondary standard. Two grant-aided mission schools were of a junior secondary standard, and it was proposed to raise these and two further grant-aided mission schools to full secondary status by the end of 1940. Tanganyika had one government school at Tabora which, while not yet of full secondary standard, was in process of grading up to that position. There were also four assisted mission schools which did some work of a secondary character. In Nyasaland and Northern Rhodesia there was as yet no secondary education. In Uganda the government school known as Makerere College was the only place at which boys had completed a full secondary education. A number of assisted mission schools were, however, providing courses of a secondary character, and it was expected that in the near future there would be three mission schools giving a full secondary course, ten or twelve giving the first three years of secondary courses, and two mission schools giving the last three years of a secondary course.

In some areas the tendency has been to give vocational teaching to pupils in the post-primary stage rather than to take them further in secondary courses of a general type. That tendency has in the past been more marked in the East than in the West African courses, but it is now being emphasized in Southern Nigeria, and has been stimulated by the policy laid down by the Colonial Office Advisory Committee.¹ The report of the East African Education Commission may, however, be regarded as a warning against going too far in this direction. It is emphasized that vocational and general education are essentially complementary, but African communities cannot progress without individuals of general cultural education.

(f) *Vocational Training*

As we have seen, recent policy has been directed to giving something of a vocational bias to primary school education, by securing that the schools should teach not only reading, writing, and arith-

¹ *Educational Policy in British Tropical Africa*, Cmd. 2374, 1925, pp. 4, 7.

metic, but improved methods of agriculture and simple village handicrafts which will facilitate the improvement of native house-building, domestic utensils, cooking, and clothing. In practice, however, the lack of control by government over primary courses, and the very short school life of a large proportion of the pupils, have prevented any wide extension of this principle. Educationists will appreciate the fact that the necessary bias cannot be given to primary teaching merely by adding a short instruction in carpentry or cooking; the whole aspect of teaching has to receive a new direction, and, as the well-known example of the Moga School has shown, this requires teachers specially trained for the purpose.

There are, however, some instances of an attempt to vary the system of primary teaching in this direction. For instance, the syllabus for the 'central schools' (these may be regarded as upper primary) in Uganda, published in 1930, allots periods to agriculture, carpentry, and instruction in the keeping of native court records and the collection of poll tax. This course was substituted for the more literary 'middle school' syllabus in several of the schools of the Church Missionary Society.¹ A marked variation from the old-fashioned literary curriculum was made in the opening in 1934 of farm schools at Namutamba and Gulu in Uganda, by the Protestant and Catholic missions. The Tanganyika Government has lately instituted 'rural industries courses' at three of the largest of its primary schools; these courses are intended to produce 'handymen' who can use their skill for their own private purposes, rather than artisans working for hire.²

In the coastal regions of the West African colonies the traditional attitude to education, as something which should be not only mainly literary in content, but modelled as closely as possible on that given in England, is more strongly entrenched than in East Africa. The report of the Under Secretary of State for the Colonies on his visit to West Africa in 1926 remarks on the extent to which education there was dominated by the 'cult of the certificate'.³ This attitude, reflecting the spirit of the period when the

¹ *Uganda Protectorate, Annual Report of the Education Department, 1930*, p. 11.

² *Report to the League of Nations on Tanganyika Territory, 1937*, p. 124.

³ *Report by the Hon. W. G. A. Ormsby-Gore on his Visit to West Africa, Cmd. 2744, 1926*, p. 90.

educational system was first established and also the natives' own preferences, finds expression in the demand for English examination standards and for the widest possible use of English as the medium of instruction. In Southern Nigeria, with the exception of King's College at Lagos, which from its inception in 1909 provided a full secondary course up to the English School Certificate, and of some secondary work done in the large mission schools, the general education given up to 1929 was a primary course, culminating in an examination which qualified for junior government posts or commercial employment. Proposals made by the Director of Education in that year led later to the reorganization of the system by division into primary and middle schools, the latter giving training of various types, which includes workshop practice and agricultural instruction, closely connected with the teaching of biology. Farms are attached to the two government middle schools outside Lagos. Schools preparing for the new school-leaving examination must teach some kind of manual work, but the course is not intended to be vocational in the sense of training for specific occupations, as it is not felt that the demand for boys with a technical training is sufficient to justify government provision for it. In the Gold Coast the effect of modern conceptions of educational policy can be seen in the greater proportion of manual work done in the Northern Territories, where the schools are of more recent origin. Generally speaking, however, much of the teaching in the western coastal areas retains its original character. It is characteristic that a large mission school in the Gold Coast could in 1938 appeal for assistance in England on the ground that it performed a Greek play every year and 'rendered the odes in the original Greek'.¹

In addition to the vocational bias in general education there are schools which train their pupils for employment in specific occupations. Here again there is a confusing conflict of nomenclature, but it will be convenient to follow the broad division drawn by the East African Commission of 1937 between 'trade schools', training artisans, and 'technical schools', organized to produce foremen and similar grades.² An alternative differentiation, which may become clear as education develops, is that the trade schools

¹ *The Times*, May 31, 1938.

² *Report*, op. cit., Colonial 142, 1937, p. 63.

should take children from the primary schools and the technical schools should recruit their pupils from the secondary schools. The Commission suggests that trade schools should be controlled by the technical departments, but technical schools by the Education Department.

There are many examples of successful trade schools. In Basutoland, for instance, the Lerothodi School concentrates on iron and carpentry work. Pupils from Bechuanaland attend the Tigerkloof Industrial School, with financial assistance from government.

Training in carpentry, building, printing, in medical work and in other technical subjects or crafts is provided at many mission stations. Most mission hospitals train male and female assistants and the missions provide courses in midwifery at many stations.¹ In Northern Rhodesia a Government Trades School at Lusaka provides a four-year course in carpentry and building (fifty-four apprentices were in training in 1935), and the Barotse National School has twenty-two carpenters and five building apprentices in its industrial department; industrial training is also given at four mission schools. In Nyasaland valuable training in building and carpentry is given at the Livingstonia Mission at Kondowi and at the Church of Scotland Mission at Blantyre. Men trained at these institutions are to be found working throughout the Rhodesias and the Union of South Africa. The Veterinary, Posts and Telegraphs, Public Works, Printing, and Transport Departments of Nyasaland have courses for training in their own branches of work. In Kenya the Native Industrial Training Dépôt, a government institution, gives artisan training organized on the basis of a four-year course, which is intended to be taken on the completion of the primary course. The dépôt provides for instruction in carpentry, smithy work, bricklaying, masonry, painting, and tailoring. In Tanganyika the Bukoba Central School was converted in 1933 to an agricultural school giving special attention to coffee; it aims at the training of farmers rather than of agricultural instructors. Five of the primary schools have artisan classes, the course in some cases running to five years; the technical training for government service is given by the Printing, Railway, Post and Telegraph, Mines, Medical, and

¹ See Chap. XVII, p. 1187.

Sanitary Departments. In Uganda the government organizes special agricultural courses of different grades for adult natives at the two experimental stations, Bukalasa and Serere. In Sierra Leone there are two trade schools in the colony; the Sir Alfred Jones Technical School gives instruction in carpentry, and the agricultural school at Mabang gives a three-year course to boys who have reached the sixth or seventh standards in primary schools.

A number of examples may be mentioned of 'technical schools', or institutions approximating to that status. The Uganda Government technical schools at Kampala and Elgon, for instance, may be accounted as such. In Nigeria agricultural schools exist at Ibadan in the Southern and Samaru in the Northern Provinces. Pupils at Samaru are expected to have already passed through secondary schools. The course given at Ibadan follows two years' training at the Yaba Higher College,¹ and therefore may be assumed to fall within the category of 'higher education'. The Katsina College in Northern Nigeria has classes which give preliminary instruction to pupils proceeding to apprenticeship with the Medical Department, or to the Samaru agricultural station; arrangements have recently been made for the training of engineering assistants in co-operation with the Department of Public Works. In the Gold Coast the Prince of Wales College, Achimota, occupies a peculiar position in that it covers every stage of education from the infant school to the university: its work on the vocational side is described in a subsequent paragraph. There is a government institution for training in agriculture and forestry at Cadbury Hall, Kumasi. This conducts a three-year course; almost all the students who take it enter the Agricultural and Forestry Departments. Short courses varying from three months to one year are also given to young men wishing to take up farming.

Within the cadre of the public services, technical and specialist training is given, as has been shown, by Public Works, Forestry, Medical, Veterinary, and Survey Departments, also in the various government printing works and in government railway shops.

Some account of the 'Jeaues' system has already been given in

¹ See below, p. 1249.

connexion with Southern Rhodesia, and it is further dealt with in the subsequent section on the training of teachers.¹ The Nyasaland Jeanes school gives some training to selected chiefs and their wives, and it is suggested that courses for agricultural demonstrators, peasant farmers, cattle masters, and clerks for the native authorities should be instituted at the centre in Northern Rhodesia, together with special courses for different branches of government service and possibly for men required by the mines.

(g) *Higher Education*

For post-secondary education the High Commission Territories look naturally to Fort Hare;² provision is made at Makerere in Uganda, the Yaba Higher College near Lagos, Achimota in the Gold Coast, and Fourah Bay in Sierra Leone. These latter colleges were founded with the intention that students should ultimately be able to reach the standard required for an English university degree. Makerere College and its associated institutions³ are the only centre for advanced education in East Africa. In 1935, 1936, and 1937 numbers of its students obtained the Cambridge School Certificate, and some of them qualified for exemption from London Matriculation; but the standard of Makerere and its associated institutions is not to be measured by this alone, for the vocational courses already take their students far beyond the level of the British School Leaving Certificate. The number of students pursuing the general cultural course represented by preparation for the Cambridge Certificate is a small minority of the total; the rest are following the vocational courses which Makerere and its associated institutions provide in medicine, teacher training, engineering, agriculture, and veterinary work. Students trained in the pre-vocational science course at Makerere and at the Mulago Medical School⁴ become fully qualified medical aids, and 'are capable, under some supervision, of running small district stations and hospitals by themselves'.⁵ The East African Education Commission recommended that the existing post-secondary courses at Makerere and its associated institutions should be grouped to-

¹ See below, p. 1250.

² See above, p. 1218.

³ Mulago Medical School, Kawanda Agricultural School, and Old Entebbe Veterinary School.

⁴ See Chap. XVII, pp. 1183-5.

⁵ *Report*, op. cit., Colonial 142, 1937, p. 97.

gether to form a Higher College of East Africa. The Government of the United Kingdom have indicated their intention of asking Parliament for a grant of £100,000 towards the cost of this proposal.¹ Tanganyika is also prepared to grant £100,000 towards it and Uganda up to £250,000. It is hoped that, as the standard of the secondary schools improves, the School Leaving Examination (or a local equivalent) will become the entrance to the proposed Higher College in Uganda, which will then develop its university studies, including courses for the London degree.

The courses now given at the Yaba Higher College originally started in 1932, in connexion with King's College. In 1934 the present college moved into its own buildings at Yaba. The courses at present offered are medical, agricultural, engineering, surveying, and teacher training. The college aims at ultimate university status, and although at present there is no arts course, it gives a course for teachers in history, literature, and Latin. The medical course, conducted in connexion with the adjoining Government Medical School, is of importance;² it aims at giving a training which will fit Africans for employment as medical assistants. As a general policy, numbers in the vocational courses at Yaba are limited to those for whom employment is likely to be available.

While Makerere and Yaba have thus the appearance of institutions framed to supply certain defined needs of the administrative and teaching bodies, Achimota is the concrete expression of the faith of coastal West Africa in higher education of a type which more closely resembles that of the older English universities. It was built at an impressive cost; begun in 1925, it was completed in 1931 at an outlay of £617,000; the annual grant for its maintenance, at first £68,000, was later reduced to £48,000. Financed almost entirely by government, it is controlled by a council of fifteen members, of which six must be Africans. The Christian religion forms a voluntary but an integral part of its teaching. Its aim has been described as the production of a type of student who is Western in his intellectual attitude towards life, but who remains African in sympathy. It seeks accordingly to preserve and develop what is deserving of respect in tribal life, and its founders hoped

¹ *The Higher College of East Africa, Proceedings of the Inter-territorial Conference, 1938*, p. 9.

² See Chap. XVII, p. 1184.

that in this respect it would afford a model for all education in the colony, and would indicate the standard which it should attain. It was with that end in view that it was decided that the college should provide a complete course of education from the kindergarten to the university degree; and it has, therefore, only in part the character of a university institution. It already offers arts and science courses covering the syllabus for the London Intermediate Examination, and provides the full course of the London B.Sc. in Civil Engineering. In 1935 there were seventeen students taking university courses. Though its avowed aim is not vocational, the subjects taught in the advanced classes include agriculture and a preliminary medical course. All pupils receive manual training in the form of 'arts and crafts' lessons and of 'hobbies' chosen by themselves. Schemes of village improvement are worked out and put into practice by parties of students in neighbouring villages, and a special agricultural course leading up to the establishment of the student in a model holding is now under consideration.

There remains to be mentioned the Fourah Bay College in Sierra Leone, which was the only institution for higher education in West Africa until the foundation of Achimota. It has given university courses in arts and theology for at least fifty years, and some of its graduates occupy prominent positions in the professions on the West African coast. It is a small institution maintained entirely by mission funds, and is affiliated to Durham University. In 1935 it had seventeen students, mainly in theology.

(h) Teacher Training

Facilities for the training of teachers are developing, but much remains to be done, and at present perhaps a majority of the teachers in primary schools have had not more than a primary education themselves and are inadequately trained. In most territories a government examination for a teacher-training certificate is imposed, and the standard of the tests is raised as training improves.

In Northern Rhodesia teachers are trained at twelve mission centres, and at the Jeanes School at Mazabuka;¹ eighty-three

¹ See below, p. 1252.

elementary teachers passed out from the schools in 1936. In Nyasaland teacher training is given in thirteen mission 'normal' schools and at the Jeanes School. In Tanganyika licences to teach have been issued to 1,496 Africans; in 1937 the department had registered 123 in Grade I, and 1,117 in Grade II, with 32 women. Training is given by various missions, but the adequate supply of well-trained teachers for the native administration schools presents a yearly problem; a special course has been opened at the Mpwapa Government School, but it can in the next three years produce only 50 teachers out of the 150 for whom requests have been made. The training of teachers in Kenya is exceptionally backward, and the system of giving instruction in teaching to students while still in primary schools is admittedly unsatisfactory. It is now proposed to form special mission training schools.

Teacher training in Uganda is more advanced than elsewhere in East Africa; in 1936, 316 men and 197 women teachers were in training at one government and thirteen mission schools. In many of these centres the educational qualifications of the teachers on entrance to the course are inadequate, the classes are said to be too large, and there is a lack of practising facilities. The government centre at Makerere aims at the higher training of schoolmasters for government service and for the missions, and serves as a model training school for the mission centres. Nigeria has a more developed system than the East African territories. There are four government training centres in the Southern Provinces, mainly for teachers in native administration schools, and training courses are also given at the Yaba Higher College. In the Northern Provinces there is a centre at Kaduna. In the Gold Coast, Achimota trains teachers for government schools and for missions which have no training facilities, and there are three mission training centres; the course of training covers a period of four years. In Sierra Leone, Fourah Bay College trains teachers for a government teacher's certificate. In the Protectorate a mission institution provides a course designed to train teachers as well as evangelists.

The training of women teachers in all the territories remains to a great extent in the hands of the missions, and training is usually on the lines of the pupil teacher system. In Kenya it is said that

there are no facilities for training women teachers, partly owing to lack of girls with sufficient education. However, in Uganda, where the education of girls is more advanced than elsewhere in East Africa, six normal schools train Grade A women teachers, and at nine centres courses are provided for vernacular teachers for elementary schools.

The East African Education Commission recommended¹ the development of government training on the ground that the native administrations are unable to depend entirely on mission centres for their teachers, and because the missions alone cannot hope to train teachers in the numbers which are needed. The Commission also urged that the standard of certification should be raised,² and that no grant should be given to missions for teachers' salaries except where a definite standard is reached. They also suggested an extension of the existing systems of refresher courses. They have pointed out, however, that the formation of a cadre of efficient native teachers depends not only on training facilities, but on salary scales. At present a cook boy can earn 30s. a month, and a third-class constable 36s., while Grade A teachers in primary schools start at only 25s. a month, and Grade C teachers have no incremental scale, and receive on an average 8s.;³ thus the teaching profession is often looked upon as a stepping-stone to better paid employment, and the wastage caused by trained men who leave after only a short period of teaching is considerable.

As an outcome of the Phelps-Stokes Commission⁴ and through grants given by the Carnegie Corporation, a Jeanes school, the first of its kind in Africa, was started at Kabete in Kenya, in 1925, on the lines already described in connexion with Domboshawa;⁵ another was established at Mazabuka in Northern Rhodesia, and another near Zomba in Nyasaland. It has already been mentioned that the scope of these schools is being considerably widened. In many quarters the work of these teachers has been held to be of very great value; in some others it has been felt that results have not come up to expectation. The difficulties in training men whose previous schooling was often inadequate are obvious, and

¹ *Report*, op. cit., Colonial 142, 1937, pp. 46, 49.

² *Ibid.*, p. 45.

⁴ *Education in Africa* (ed. T. Jesse Jones), 1922.

⁵ See above, p. 1228.

³ *Ibid.*

the deliberate encouragement of such men to become 'leaders' is said to give them a feeling of superiority and a preoccupation with their salaries and status which reacts unfavourably on their work. In the case of the mission-employed Jeanes teachers there is also a tendency for their loyalties to be divided between their employers and the government which controls them through post-training supervision. A full account of the movement is contained in the Report of the Inter-territorial Jeanes Conference held at Salisbury, Southern Rhodesia, in 1935.¹

(i) *The Dependence on External Examination Standards*

When African schools, conducted by missions and governments, felt it necessary to enter their pupils for external examinations, they followed the obvious course of asking the examining bodies which set examinations for schools in England to extend their work to Africa. Two important factors accelerated this process; Africans attached the greatest importance to tests which carried an English hall-mark; and almost all professional qualifications to which an African might aspire could only be obtained by candidates who had passed a British school leaving examination or university matriculation.

This development imposed upon African secondary schools a curriculum which, devised for English children, was unsuitable. In the primary schools, teachers, preparing their best pupils for secondary work, adapted their syllabuses to the needs of the external examination, and in doing so imposed the influence of that examination upon numbers of African children who would never pass beyond the primary stage of education. These effects are now well realized and in most of the dependencies efforts are being made to counteract them; but in some of the coastal areas of West Africa the change is delayed by the opposition of Africans to any step which appears to deprive them of gaining the hall-mark which a pass in an external examination is held to convey.

The English examining bodies, of which four are concerned, have been helpful in the matter. At the invitation of the Colonial Office they have formed a Joint Advisory Board for School Examinations in the Colonies and Dependencies. Through this

¹ *Village Education in Africa*, 1936.

Board an agreement has been reached which rules out undesirable competition between the examining bodies. The Cambridge School Examinations Syndicate and London University have taken local circumstances into account in adapting their requirements to African needs. For instance, in the Gold Coast, agricultural science and four African vernaculars may be taken as subjects in the school leaving examination. Special botany papers are set, mentioning only local plants. At Achimota the practical subjects for the London degree in engineering are tested by local examiners under local conditions.

At the same time something has been done in East Africa to provide examinations locally. For instance, the Joint East African Examining Board in Medicine conducts examinations in pre-vocational science (approximately of school-leaving standard) and in more advanced subjects.¹ The East African Education Commission² recommended that an East African School Leaving Certificate should be instituted and granted by a joint board representing the Education Departments of the four East African dependencies.

It is obvious that adjustments of the external examination, such as those referred to above, cannot have more than a partial value. So long as the external examination is allowed to be the end towards which secondary education works, it must tend to influence the whole outlook of African education. It will have another effect, the bearing of which may become more important in the future than it is to-day.³ It will make it increasingly difficult to consider the use of any of the African languages as a medium of secondary or advanced teaching. In the present state of African education, however, it must be admitted that the external examination has a definite function; it serves both to check the standard of the local tests, lest they stagnate or fall, and lose the respect of Africans and Europeans alike, and to provide an avenue for Africans to enter certain professions which otherwise would be closed to them. Viewed in this light, it follows that the local examinations should be those normally taken, and that the oversea examinations should be confined to a small class of selected students.

¹ Chap. XVII, p. 1185.

² *Report*, op. cit., Colonial 142, 1937, p. 60.

³ See below, p. 1257.

(j) Education of Women and Girls

The general policy for the education of women and the facilities for training women teachers have been mentioned above. Prejudice and social custom, also the lack of women teachers, present difficulties; but that a desire exists among many classes of Africans for the education of their women cannot be called in doubt.¹ Educated men feel the need for wives who can help them in the leading positions they hold in native society. In the case of teachers, an attempt to meet this need is made by the provision of special training for wives at the Jeanes schools and at many mission stations. The share women take in almost every activity of tribal life, and their great influence in agricultural as well as home matters, emphasize the need and importance of adequate schooling for girls.² Again, the large numbers of women and girls who now live in urban areas, in mine compounds, or on the properties of the European employers of their husbands or fathers, divorced from the daily routine of village and tribal life, would seem to create an educational problem calling for special attention.

An examination of the educational figures shows that throughout most of British Africa the education of girls has lagged behind that of boys. Exceptions to this generalization can be found in Basutoland and Bechuanaland, where, owing to the long absence of the young boys herding cattle, the number of girls in school is twice that of boys. The salient characteristics of the present position elsewhere in British territory may be briefly summarized, but here again it is necessary to emphasize the considerable amount of work done on mission stations apart from officially recognized or state-aided schools. There are few stations where some girls or women are not receiving a valuable if limited training in the domestic sciences or in the care of children, in nursing and midwifery, or as teachers.

In Northern Rhodesia the number of boys and girls attending school is almost equal; the great majority of the girls, however, attend sporadically at 'ungraded' schools, where they receive little serious education. There are some twelve boarding-schools managed by missionary societies; one of these, the Mbereshi

¹ *Report*, op. cit., Colonial 142, 1937, p. 66.

² M. C. Blacklock, op. cit., pp. 232 ff.

School of the London Missionary Society, trains girls as nurses, and a Jeanes school for girls gives an education which prepares for marriage and motherhood. This school is subsidized by the Carnegie Corporation and the government. In Nyasaland the average attendance of girls in schools going beyond the elementary vernacular stage in 1935 was 639; the enrolment at teacher-training institutes was eighty-seven and in medical classes seven. In Tanganyika fourteen mission schools for girls receive assistance from government. The first government girls' schools were opened in 1929: there are now three, but there is a considerable number of co-educational primary schools. In 1937 the pupils in government or recognized schools numbered 2,999. The government is about to appoint a woman officer as supervisor of the education of women and girls. Kenya in 1935 had 29,011 girls in elementary and 399 in primary schools. In Uganda, King's College at Budo provides an experiment in co-education, though there are only 22 girls among 300 pupils.

In Southern Nigeria there are one government and twenty-five assisted girls' schools. The government school, Queen's College, Lagos, is a secondary school. Three girls obtained the School Certificate in 1934, and earlier pupils have done well. One girl passed into the University of Dublin and is taking a medical course there. A few mixed schools provide courses in domestic subjects for girls; a 'housecraft certificate' is offered for older girls. In addition a number of missions manage 'marriage-training homes'. In Northern Nigeria it was not till 1929 that the Moslem prejudice against the education of girls could be overcome. There are now five girls' schools with an increasing number of pupils. In the Gold Coast there are three government and eleven assisted girls' primary schools, and twenty mixed schools teach domestic science. The only girls' secondary school is Achimota: here two Gold Coast girls for the first time obtained the Cambridge School Certificate in 1934. A few African girls are now entering higher educational institutes, and are qualifying for university degrees and diplomas.

(k) *The Education of Chiefs*

The attempt to secure an educated class of native rulers led to the establishment in British territories of three schools originally

intended for chiefs' sons, at Georgetown in the Gambia, Bo in Sierra Leone, and Tabora in Tanganyika. The Bo school was founded in 1906 and at one time had representatives of eighty-seven chiefdoms on its rolls. The eight-year course was mainly literary, but gave some attention to agriculture. Tabora at one time attracted much attention as an experiment in education on tribal lines; the pupils lived in boarding-houses grouped according to the areas from which they came. A similar organization was introduced at other 'central' schools in Tanganyika, notably Malangali, but has now been abandoned. With the general spread of education it has been considered unnecessary to reserve special institutions for the families of chiefs, who now receive their education in the ordinary schools. Some doubts have, indeed, been felt whether it is really within the spirit of native institutions to do anything which would mark the chiefs out as a separate class. The course for native authorities at the Jeanes school in Nyasaland represents a more modern attempt to deal with the problem of training chiefs in their new duties. In general, however, it is now left to solve itself through the increasing demand for education and the prestige of the educated. As will be seen, the French¹ and Belgian² systems both make special provision for chiefs' schools; that the British authorities have ceased to maintain such schools is due not to any lack of appreciation of the value of education for chiefs, but to a different conception of the functions which chiefs have to discharge and the position which they occupy in their own society.

(1) The Language of Instruction

The language to be used as a medium of instruction, and the stage at which the teaching of English, or of a useful and widely spoken language such as Swahili, can be introduced, present complex problems. The diversity of native languages is considerable and large language groups are the exception rather than the rule. The measures taken to meet this difficulty have been described.³ An important factor is the desire of Africans themselves to learn English, which in many cases is the incentive to seek education.

¹ See below, p. 1266.

² See below, p. 1277.

³ See Chap. III, p. 98.

A knowledge of English is of commercial value, for at the mines, the trading stores, and on European estates the English-speaking native can often command a better position and a higher wage. Again, there is the natural desire of the African to learn a language which is that of his rulers; the scarcity of general literature in the vernaculars is not without its influence in this direction among a people to whom reading is a new-found pleasure.¹ The weight of native opinion has sometimes led schools to attempt the teaching of English in early standards through inadequately equipped teachers, a system that leads to discouragement. The general practice now follows that indicated in the memorandum of the Colonial Office Advisory Committee² and a native language is used in the elementary stages, but there is still considerable difference of opinion as to the point at which English as a subject or a medium should be introduced.

In Nyasaland the vernacular is the medium of instruction during the first four years in primary schools. English is then introduced as a subject in lower, middle, or central schools for three years and becomes the medium of instruction in upper, middle, or station schools. In Kenya, Tanganyika, and Uganda the use of Swahili as a convenient language in place of the local vernacular is common. In this connexion the policy put forward by the Director of Education in Uganda is important, and indicates a tendency in Uganda to replace Swahili by the vernacular or even English. The Director advocates the use of the vernacular as a medium of instruction during the first four years and the introduction of English as a subject in Class IV, the emphasis on the vernacular decreasing until English becomes the medium; Swahili should be permissive and introduced only if desired as a subject in Class III. This is in effect the practice obtaining in Buganda and Busoga, and it is suggested that it should be extended to some other linguistic groups. In Kenya, Swahili is introduced as a medium of instruction at the third or fourth standard between the vernacular and English, as a solution of the difficulty of providing instruction in a vernacular to pupils of mixed tribes speaking different languages in schools which are

¹ See below, pp. 1294-6.

² *The Place of the Vernacular*, op. cit., African 1110, 1927, p. 8. See p. 1230, above.

not advanced enough or equipped with staff qualified to use English as a medium. In the native administration schools of Tanganyika, Swahili is the medium and English is not taught; in the government and mission primary schools, however, Swahili is the medium for the first four years only, after which English becomes the medium. In Northern Nigeria English is the medium at the 'middle' or secondary stage. For pupils whose primary education has been entirely in the vernacular, a preliminary year is devoted to the intensive study of English. In the Gold Coast English becomes the medium after Standard III. Although it is generally recognized that the introduction of a second native language as a medium, or the usage of a lingua franca instead of the local language is far from ideal, and also that it is important not to alienate the native from his mother tongue, the difficulties of providing teachers and text-books in the vernaculars and of instruction to mixed classes are in some areas insuperable.

(m) *European and Indian Education*

The West African territories do not have to make provision for European education. In all other areas, including the High Commission Territories, there are European schools, though only in Kenya and Northern Rhodesia are they on any considerable scale. The changes following the report of the Education Commissioner¹ in 1936 are bound to reflect on the Northern Rhodesia system of European education, which is closely connected with that of Southern Rhodesia.² At the age of 12 years and 15 years Northern Rhodesia children may take public examinations entitling them to scholarships and bursaries financed by the Beit Trustees. The latter examination leads to a further three-year course at a Southern Rhodesia secondary school. Northern Rhodesia schools at present provide two years of a secondary course. There is no provision for technical education, but the Technical School in Bulawayo can probably serve both countries efficiently for some time to come. In the north, as in the south, academic secondary education is also said to be unsuited to the majority of children, but there is a demand by the European population in the north for further provision for secondary and technical education, though there is much to be

¹ C.S.R. 25, 1936.

² See above, p. 1224.

said against it.¹ The attendance at European schools in Nyasaland has diminished rapidly since 1935, when Southern Rhodesia abolished all tuition fees, and extended this privilege to children from Nyasaland. There are in Tanganyika government-aided schools giving elementary teaching in English, German, and Greek. For secondary education the pupils have to go to Kenya, which admits children from all the East African territories into its secondary schools.

Schools for Asiatics are maintained in Kenya, Uganda, and Tanganyika, as has been explained in Chapter VIII.

V. THE FRENCH TERRITORIES

(a) *Evolution and Character of French Colonial Education*

At the outset French policy was limited to the grant of assistance to missionary effort. The earliest instructions, issued from the Colonial Ministry in 1816, justified the encouragement of Christianity on the ground that its moral basis would make for progress in civilization. In spite of the resistance which this policy encountered from Moslems in Senegal, it regulated educational effort for forty years, and the government showed its own interest by founding a college at St. Louis for the training of priests. The progress made was slow, and by 1854 there were only four schools, situated in the old settlements of Gorée and St. Louis, with a total number of 600 students. The more vigorous policy of Faidherbe, in which internal development was combined with external expansion, effected a change. In 1857 he founded the first lay school, and Galliéni subsequently opened a similar school in each of the towns which he occupied in the French Sudan. But even under the new policy the advance made was not substantial; there were in 1900 only seventy schools in French West Africa, with an enrolment of 2,500 pupils, while the only schools in the Ivory Coast and French Guinea were those still carried on by the missions. In part this was due to the preoccupation of the government in the pacification of the Sudan and Senegal, but in the main the reason must be sought in the fact that France had not yet clearly envisaged

¹ See *Report of the Commission on the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, p. 277.

the education of the African as an active factor in producing that approach to French civilization which is the objective of modern French policy. To-day British observers of the French system of education in Africa cannot fail to be struck both by its distinctive conception of the political function of education and by the systematic character of the steps taken to give effect to that conception. Education has a definite place as a factor in the policy of association.¹

While in British territories more attention has, until recent years at least, been devoted to the expansion of education, there have always been differences of opinion as to its objective; nor could it be said that the assumption by the State of responsibility for its control has yet resulted in any such precision in its objective or its methods as has followed from the decision of the French to define its place in their political system. In their colonies the principles are laid down by the Colonial Ministry, in close touch with the Ministry of Education, and their execution is ensured through the ministerial inspectorate. Although a good deal of latitude is allowed to the local governments in administration, the system of education has the uniformity of a centralized organization, and affords an illustration of that logic of method which has led one of their own authors to describe the French as the 'drawing masters of Europe'.

(b) *French West Africa*

The points of contrast will appear more clearly from a study of the system as now in operation in French West Africa. The organization first set up by the local *arrêtés* of 1903 was revised in 1918, but in its present form it is based on the general orders contained in the circular of the Governor-General of May 1, 1924. The State assumes the major responsibility for education, and while subsidies are granted to missions the part which their schools play in the system has little influence on its development; out of a total of 62,300 primary pupils in 1935 there were only 9,458 in non-state schools. While the French Government was a party to the Treaty of St. Germain of 1919, which guaranteed freedom of conscience and the right of missionaries to pursue their calling, it stipulated

¹ See Chap. IX, p. 484.

in a decree issued in February 1922 that no private school should be opened without authorization, that authorized schools must undertake to follow the courses prescribed by the state, that education must be given exclusively in French, and that European mission teachers must have the same certificates as government teachers. Some latitude is observed in practice in applying this decree; but the state is prepared to support the mission school only in so far as it affords instruction in the French language and develops sentiments of loyalty to France. The education given in the state schools is entirely secular. There are two parallel systems, the European and the African. In the former the curriculum is identical with that given in the schools of France, so that a child can at any time transfer from one to the other, and a pupil who has completed the course provided in Africa is qualified for entry to French universities or technical institutions. In the latter the programme is intended to be a training for life in Africa. The dual system, however, does not correspond to a colour bar, nor to a classification of school children on a basis of colour. French-speaking African children attend the French schools, and in Algiers, where the organization is similar, the children of poor French families go to the African schools. It is not easy to exaggerate the effect on native outlook of a system which permits Africans to sit side by side with French children and to compete with them on equal terms in school examinations.

It is, however, to the African schools that chief interest attaches for the purpose of the present survey. Educational policy is marked by two outstanding features: first, the universal use of French as the medium of instruction; secondly, a clearly defined policy of limiting more advanced education to the demand which exists for its products, with a strong emphasis on vocational training as the form which such education should take. The use of French as a medium of instruction from the earliest stages is supported on the ground that if mastery of a European language is the ultimate aim, it is better to start it as early as possible. The pupil is instructed by the 'word method', that is, by associating the appearance of the whole word with its pronunciation and meaning, rather than by trying to read or write it syllable by syllable. Given the objective, the French method certainly

appears to be successful in imparting a knowledge of the language and an ease in using it which is remarkable even in the early stages of study. As for the second point, the policy of maintaining a relation between the demand and supply in the higher branches of education is not merely a doctrine of expediency, nor is it entirely due to a desire to avoid the creation of that large and discontented class of educated unemployed to which many point as the first-fruits of the educational policy of India. It is founded on the belief that the fuller association of the native population in the development of a territory can best be realized through the employment in the administrative service of those whose intelligence qualifies them to share in spreading the work of civilization. The first object of advanced education is, therefore, to train the specialist cadres needed for this purpose. Education accordingly assumes a dual function; this has been summed up in the well-known phrase of a former Governor-General, M. Carde, '*instruire la masse et dégager l'élite*'.¹

Thus the French policy aims at providing for the majority of the school population an elementary education complete in itself, and limits the number who proceed to more advanced courses; entry to secondary and higher institutions is gained by competition, and the numbers turned out are restricted to estimated needs. In this way the domination of the school system by the most advanced institutions, characteristic of some British territories, is to a large measure prevented. It is further characteristic that state education is throughout free. Even in the boarding-schools all charges are met by the state, which gives a small sum as pocket-money; all students are taught to consider themselves as stipendiaries of the state. The 'popular' schools, as those designed for the masses are called, are of three grades—'initiation' or preparatory, elementary, and lower primary. Schools of the first grade are to be found in most villages of any importance, and teachers even accompany groups of nomad herdsmen. These schools give a course of two years, concentrating almost entirely on spoken French. There is an elementary school in every town and at nearly every government station. In the rural areas the teaching given concentrates on the improvement of local conditions;

¹ See Chap. IX, p. 484.

in addition to instruction in agriculture and animal husbandry, attention has been given to the development of local pursuits special to certain districts, such as metal-working in the Siguiri gold area, and fishing on the coast. In 1935 there were 273 village and 19 urban schools of this type with 29,294 pupils.

The primary stage is represented by the regional schools, the majority of which have European headmasters. Much of the success of the French system depends on the work of these masters. They belong to a different class from the officers in the British educational service, and live on terms which bring them into closer touch with Africans; all observers agree in recognizing the enthusiasm and professional skill which they bring to their task. Seventy-eight regional schools, attended by 23,312 pupils in 1935, give a further two years' education, carrying history, geography, hygiene, and arithmetic beyond the point reached in the elementary school, and combining them with training in farming and carpentry of the kind adapted to village life. In the towns, at the corresponding stage, urban primary schools give a course which is almost entirely literary, since their pupils may expect to find employment in clerical work. For the two normal schools which train teachers for rural work sites have been chosen in the Sudan and the Ivory Coast as representing the two typical climates of French West Africa. Urban teachers are trained at the William Ponty School at Dakar. The 'popular' course is complete with the primary school. In addition, however, there are in the larger centres, craft schools, taking pupils of any age, whose aim is to improve the technique of indigenous crafts; trade schools which are open to any one with elementary education and to trained mechanics, masons, chauffeurs, &c.; and adult courses concerned mainly with agriculture and hygiene, which are given in the vernacular. In 1935 about 200 such courses were organized and attended by 8,400 natives.

The Mission Schools. Though the French educational system does not depend, as has already been shown, upon mission activity, there are a number of schools managed by missions. Many of these are 'bush' schools, where the teaching is mainly confined to oral and religious teaching in the vernacular, but there are also some which teach up to the primary standard in the European system, such as the White Fathers' primary school in Dakar. In Togoland,

where the provisions of the mandate require that freedom of access be granted to all missionaries who are nationals of states members of the League, mission activity is proportionately greater; in 1937 there were fifty-one government schools with 5,044 pupils and thirty-eight aided mission schools with 4,974 pupils. Subsidies to missions amounted to 8.5 per cent. of the total education expenditure. Only missions which teach French are eligible for the subsidy, which is based on the amount expended on teachers' salaries; but teachers need not have French qualifications, and may use the vernacular as the medium.

Education of Girls. In the Sudan and Senegal there is a certain number of schools for girls, and one in the Ivory Coast at Grand Bassam; there is also a large number of mixed schools. At Bamako and Ouagadougou there are orphanages for half-caste girls, the state regarding the education of the *métis* class as a special responsibility. In the regional schools the training of girls in household management is being developed. The total number of girls receiving education is, however, small; in 1935 there were 2,060 in village schools and 2,309 in regional schools. There were twenty-one girls at the *Lycée Faïdherbe* and 141 at the Dakar Secondary School, fifteen in the midwifery and five in the district nursing section of the Dakar Medical School.

The Chiefs' Schools. There are now four schools for the education of chiefs' families. The chief, as is shown elsewhere,¹ is in the French system regarded essentially as an agent of the administration, and it is considered necessary both to give him the administrative training appropriate to this position and to ensure, by his education in a special school, that he ranks in the class of the *élite*. In founding the first chiefs' school at St. Louis in 1856 Faïdherbe stated² that it was designed to form 'quelques indigènes d'élite pour nous aider dans notre œuvre de civilisation'. Closed for a time, it was revived, and in 1908 became an advanced Moslem school, but not confined to chiefs; it returned to its former status in 1922, entrance being limited to members of the families of Moslem chiefs. Since then three other schools have been added; in their four years' course, in which, though Arabic and Koranic law are taught as subjects, French is used throughout as the

¹ See Chap. IX, p. 486.

² *Le Sénégal*, 1889, p. 366.

medium, chief stress is laid on the study of administrative methods, including the local law and judicial system, book-keeping, and correspondence. Of late years some agriculture has been added.¹

The Post-Primary Stage. All education beyond the primary stage has in view the supply of such numbers of specialists as are needed in vocational employ. French West Africa repeats here the educational history of Madagascar. As early as 1897 Galliéni broke with the traditional literary methods, claiming that in the absence of express provision for vocational training the policy of associating natives in administration would be impracticable. In Morocco the policy of vocational education arrived later; but it is noticeable that primary education is there characterized as 'pre-apprenticeship', since it is designed to fit natives for industrial occupation in the towns and farming in the villages, while in the 'schools for the sons of the notables' there is provided a special type of education for the small class which is treated as having a vocation in local leadership. The product of vocational training is now characterized in French West Africa as the *élite*, the 'cadres who are to help us in our work of colonization'.² These cadres are formed from among the best pupils in the regional schools. Selected pupils follow a course of three years in one of the eight higher primary schools established at the centres of the eight divisions³ of the federation. These schools give a general literary education. The most successful pupils then follow a course lasting one year to prepare them for entrance to high schools. In the high schools they are prepared for the lower grades of government or clerical employment, or for entrance to the *grandes écoles*, that is to the Medical School at Dakar,⁴ the School of Administration and Teaching at Gorée-Dakar, the Veterinary School at Bamako, or the schools for training rural teachers (*écoles de pédagogie rurale*) in the Sudan and the Ivory Coast. It is also proposed to form a higher technical school. All these schools are designed to train a superior class of assistant to the European government officials. In some of the colonies the higher primary schools have a vocational side with a *section de bois* and a *section de fer*, but these give a training leading

¹ For chiefs' schools in the Cameroons, see below, p. 1270.

³ See Chap. VI, p. 189.

⁴ See Chap. XVII, p. 1185.

to minor posts in the Public Works, Postal, Railway, and other Government Departments.

The instruction given throughout all these schools is adapted to local conditions and is apart from the metropolitan educational system. On the other hand, two secondary schools, the *Lycée Faidherbe* at St. Louis and the secondary school at Dakar, a private school which was taken over by the state in 1925, are schools on a European model, and since 1924 give a leaving certificate which corresponds to the French *baccalauréat*. Scholarship pupils pass to these two schools from the high schools. A school of marine engineering also takes pupils from the high schools and gives a four-year training for naval service, including a knowledge of electricity which can be turned to account when the apprentice leaves the navy. The Medical School at Dakar, which is described elsewhere,¹ represents the most prominent educational achievement of the federation.

The system current in the mandated Togo follows in the main that of West Africa. The primary stage is completed in the regional schools which, as shown in a previous paragraph, are divided between the state and the missions; there are also a number of *écoles ménagères* for girls. In all, some 1,422 girls receive teaching of various types. Provision is made for post-primary teaching by two superior schools, opened in 1937 in Lomé and Atakpamé, both with a strong vocational bias. There is also a Togo section provided in the Victor Ballot School at Dahomey and in the Agricultural School at Porto Novo. In 1937 a series of *cours populaires du soir* were instituted on the model adopted in French West Africa.

(c) *French Equatorial Africa and Cameroons*

In French Equatorial Africa development is behind that of French West Africa. It has not yet reached the point where the dual system is necessary, and only the African course, up to the higher primary stage, is provided. There is an artisan school at Fort Lamy, and technical training is given by apprenticeship with the Public Works Department. It was decided in 1934, as a measure of economy, to send pupils to the technical and professional schools

¹ See Chap. XVII, p. 1185.

of French West Africa, rather than undertake the creation of parallel institutions for the French Congo. Only one regional school has a European teacher, but in some village schools in the military subdivisions French warrant officers are employed as instructors. In 1935 there were seventeen urban primary schools with European teachers. A school for the training of agricultural demonstrators was opened at the experimental station in Brazzaville in 1936. The attitude of government towards mission work has differed from that in French West Africa. Before the Treaty of St. Germain was ratified, local *arrêtés* laid down that only an association incorporated in France might open a school, and no school was authorized unless teaching was given in French; a circular of February 1921 emphasized the fact that the administration would enter into no relations with bodies whose constitution did not afford a guarantee of the absolute preponderance of French influence in a French country. The subsequent Decree of April 1921 conveying the ratification of the St. Germain treaty did not in terms modify the restrictions placed by previous *arrêtés* on educational institutions. In practice, however, their application has been relaxed, and there appears to be an understanding that non-state schools maintain their existence subject to the goodwill of the administration. Mission schools are subsidized, but may not teach any subject other than religion in the vernacular, and to qualify for recognition must have French taught by a teacher with a local diploma. In 1935 there were ninety state and ninety-eight mission primary schools. The total attendance at schools of all kinds was 15,877.

In the French Cameroons education is more fully developed. There are one advanced and three technical schools, one of which trains specifically for employment in the railway service and on public works, and two domestic training schools, attended in 1934 by 110 girls. There are also two mission technical schools. The higher primary school in its third year gives specialized training for clerks, postal officials, and candidates for the Medical School at Ayos, which was founded in 1933. In the mandated area mission teaching may be given in the vernacular, but only schools using French can qualify for government recognition. In 1935 there were sixty government village schools with 5,904 pupils: the

recognized mission schools had 6,610 and the unrecognized 81,758 pupils. These last are largely catechetical. Subsidies are paid on the basis of the qualifications of teachers and there is also a bonus on examination results; Catholic missions received 15,300 francs in subsidy and Protestant missions 60,600 francs. The education of chiefs follows a somewhat different course from that adopted in French West Africa.¹ There is a small establishment at Garoua for the sons of Moslem chiefs, where instruction is given by representatives nominated by the chiefs. Elsewhere the fact is recognized that chiefs have not the same social position as in the north. At Yaoundé a special class is reserved for about forty-five pupils of this type in the regional school; at Dschang and elsewhere about 252 members of chiefs' families attend the ordinary schools, but the *arrêté* of December 27, 1933, contemplates that when they have reached a suitable stage of instruction special courses will be opened for them.

VI. THE BELGIAN TERRITORIES

(a) *The Belgian Congo: the Place Assigned to Religious Bodies*

The Belgian Government has relied to a greater extent than the British upon the work of religious bodies in native education; and not only is the close contact between the state and these bodies a striking feature of the administration, but the nature of its relations with the Catholic and Protestant bodies respectively has had some significance in the political history of the Congo. The work of Christian missions had received particular consideration in the Berlin Act of 1885, which agreed that they should be accorded special protection. But the early entry of members of the French orders caused Leopold II to fear a growth of French influence, and by agreement with the Vatican the Belgian missionaries of Scheut were substituted for them. The Baptist Missionary Society under the leadership of George Grenfell and other Protestant missionaries had preceded the Catholics by some years, and had established a chain of missions along the Congo river; but the Concordat which Leopold II concluded in 1906 with the Vatican established the Catholic missions in a position of almost exclusive influence.

The Free State offered perpetual grants of land to Catholic mis-

¹ See above, p. 1266.

sions established in the Congo, and agreed to subsidize not only their scientific and educational activity but also their religious work. In the movement against the old Free State régime the Protestant missions incurred the charge of supporting English and American interests against those of the Free State, which had found some of its apologists among prominent Catholics. Under the Belgian Government suspicions of this nature have ceased to exist, but the administration continues to exhibit a preference for the Catholic bodies as agents in education. The missions are still divided officially into 'national' and 'foreign', of which the former in 1936 had 951 European and 53 African priests, 506 European and 94 African lay-brothers, 1,216 European and 114 African sisters, and 1,601,144 followers, while the latter had 893 workers and 238,807 followers. Since the 'national' missions are predominantly Catholic this gives a rough approximation of the proportion of Catholics and Protestants respectively. No mission school in the Congo is obliged to submit to inspection unless it wishes to receive a subsidy; but no subsidy can be given to a body which is not recognized as 'national'. The Protestant missions can with difficulty secure this recognition, of which the principal condition is that two-thirds of the administering body must be Belgian;¹ the British Roman Catholic missions seem to have encountered less difficulty.

The result has been that the 'foreign' schools, which in 1935 had 253,841 pupils, against 213,463 in those of the 'national' missions, are maintained almost without assistance from the state. Again, even in the few state schools, the management is almost universally entrusted to religious bodies, which are without exception Catholic. The Treaty of St. Germain and the *Charte Coloniale*² itself guarantee complete religious liberty in the Congo; but in so far as educational activity is concerned, the foreign Protestant mission is placed at some real disadvantage, under a system in which Catholicism, though not formally recognized as a state religion, enjoys so predominant an influence with the administration. The work at some of the Protestant institutions is, however, recognized by the authorities as being of a high order.

The Belgian Government, in making so wide a use of religious bodies in the management of its schools, bases itself on a view of the

¹ Decree of July 19, 1926.

² See Chap. VI, p. 206.

place of religion in education which has many points of resemblance to that embodied in the British Colonial Office Memorandum of 1925.¹ There is a typical expression of this view in the words used by M. Louis Franck:² 'pour l'éducation morale c'est sur l'évangélisation qu'il faut compter. On ne fera rien de permanent sans elle. Cette conviction est indépendante de toute considération de foi ou de dogme. Elle est basée sur cette observation que la vie indigène est profondément pénétrée de religiosité, et dominée par le mystère.' It must also be acknowledged that the administration has been able to count on finding among the religious bodies many teachers who bring not only enthusiasm but professional qualifications to their task. The *Frères de la Doctrine Chrétienne*, the *Frères Maristes*, and some of the Salesian Fathers are trained teachers, and at the vocational schools there are numerous lay brothers who have practical knowledge of the industries in which they give instruction. The practical work done in the schools at Kisantu or Baudouinville is typical of the value of this system. In entrusting education to bodies of one denomination the state can claim the further advantage of a centralized organization; as expressed by the ministerial brochure of 1925 on educational policy, 'l'esprit de corps et la continuité de vues qui prévalent au sein des congrégations enseignantes permettent d'adopter une méthode, malgré les mutations de personnel'. The Congo is for this purpose divided into areas, each of which is under the control of a Vicar or Prefect Apostolic. For the rest, it may be said here that Belgian policy assigns to the African a different cultural future from that envisaged by the French; it looks less to his association with European civilization than to his fuller development within the range of his own economic and social environment. To quote again the words of M. Louis Franck, the Belgians wish to produce better Africans; they have no wish to make copies of Europeans who will never be more than 'humans of a third category'.

(b) *The Organization of Instruction*

The earliest educational efforts were authorized by a Decree of July 12, 1890, providing for the establishment of 'school colonies' for abandoned or neglected children; a further Decree of March 4,

¹ See above, p. 1229.

² *Études de colonisation comparée*, 1924, p. 123.

1892, authorized missions to receive such children into their schools. The government for its part opened in 1906 a school for clerks and three technical schools, whose object was to train Africans for government employment; of the latter, two were attached to state workshops, the other to those of the *Compagnie des Chemins de Fer des Grands Lacs* at Stanleyville, the training given being almost exclusively manual. The Concordat of 1906 provided that every Catholic mission established in the country should open a school, subject to government inspection, and teach a syllabus agreed upon with the government, which was to include agriculture, forestry, and handicrafts. The national languages (French and Flemish) were to be taught. On the annexation of the Congo by Belgium, the technical schools were replaced by *groupes scolaires*, financed by the state, but managed by the Catholic missions, and giving both primary and technical education. The organization of a complete school system was not undertaken till 1922, when the principles now followed were drawn up by a commission including representatives of the government and missions and experts from technical schools in Belgium.

The present system comprises three grades of school—namely, lower primary, higher primary or middle, and secondary. The lower primary grade is that of the village school under an African *moniteur*, controlled by inspecting officers appointed by the mission responsible for him. Here literary instruction is reduced to the minimum. The aim is stated to be the spread of ‘moral discipline, ideas of hygiene, the ferment of progress, respect and sympathy for our colonial enterprise’.¹ These schools give a two-year course. The middle schools give a course lasting three years. They must have a European headmaster (in practice a member of a Catholic missionary body) and are established mainly at urban centres; but they draw their pupils from a wide area, and often provide accommodation for boarders. In the Eastern Province experiments were made, in areas not penetrated by missionary enterprise, in the establishment of ‘native administration’ schools, built by the local authorities and supervised by administrative officials. It was found that the latter were unable

¹ E. de Jonghe, *L'enseignement des indigènes au Congo belge*, Institut Colonial International, 1931, p. 95.

to conduct an effective supervision, and steps were taken to hand the schools over to mission control. The proposal to revive such schools elsewhere with lay teachers has been discountenanced as contrary to the general educational policy. The post-primary courses last for three years and give both general and vocational education. There is a teachers' course, a clerical course, and a technical course, which includes agriculture, woodwork, leatherwork, tailoring, printing, bookbinding, carpentry, masonry, and metalwork. The subjects taught are selected with regard to the economic possibilities of the neighbourhood, and where there is little industrial employment attention is concentrated on training which can be turned to account in village life. Special *écoles ménagères agricoles* for girls teach sewing, cooking, agriculture, and child welfare.

The general school system is divided into 'official' and 'subsidized free' schools. The 'official' schools are financed entirely by the state; the majority are controlled by the religious orders, though there are a few directly under the management of government departments. There are also six schools for medical assistants, of whom an increasing use is made in the Congo, and four for midwives, managed by the medical service,¹ while the *Force Publique* organizes a number of technical courses. In 1935 the official schools numbered nine for boys, which gave some post-primary instruction, with 4,674 pupils, and two for girls, with 1,017 pupils. Subsidized schools for boys numbered 4,343 with 191,636 pupils, and for girls 209 with 16,968 pupils, in addition to eleven special girls' schools in urban centres, with 2,643 pupils. There were five teacher-training schools for girls, twenty-one for boys, four schools for training clerks, two technical schools, and eleven domestic economy (*ménagère*) schools for girls. There were also fourteen schools for European children, managed by missionary bodies. Inspection is in the general charge of a state Inspector-General, with an inspector in each province; but the major part of the detailed inspection of schools is carried out by missionary-inspectors, who report to the state inspectorate. As in the French territories, all education is free, even in boarding and technical schools.

¹ See Chap. XVII, p. 1192.

Some of the large industrial enterprises maintain their own educational institutions.¹ In the Katanga, the *Union Minière*, as part of its policy of creating a stabilized industrial population, has opened primary schools at six important centres, attendance up to a certain age being compulsory. Boys who do not go on to a technical school are kept at agriculture till they are 16, when they are apprenticed at the mines or in some other employment. These schools had 1,102 pupils in 1935. The *Huilleries du Congo Belge*, as a condition of their concession, maintain a school in each of their five circles; these schools attain a high standard of efficiency. Some schools are financed by the Kilo-Moto Company. The teaching in all these schools is given by Catholic missionaries. Some of the larger companies have also opened technical schools with the object of replacing European by African skilled labour. The Bas-Congo-Katanga Railway established four such schools in 1921, for engine-drivers, artisans, station clerks, and foremen of repair gangs, which draw their pupils from the more promising employees of the company; by the end of 1932 over 2,000 men had taken training courses. All the transport companies now organize such training. The *Union Minière* has had since 1922 a school with sections for carpentry, ironwork, engineering, and the repair of locomotives.² Both the *Union Minière* and *Forminière* train dispensers for their hospitals.

The organization of this type of instruction represents a philosophy markedly different from that of some other administrations in Africa. It is the antithesis of that which has produced the colour-bar legislation in the Union, since it seeks to recruit the ranks of industry from natives trained to exercise all the mechanical skill of which they can show themselves capable. One of the outstanding impressions left on any observer of the Belgian industrial system must be the wide extent to which the native is entrusted with the charge of machinery and is employed in work requiring technical knowledge. But at the same time the Congo Government has hitherto shown less desire to create that class of skilled 'auxiliaries' in the technical departments of government, which is the most characteristic product of the French system. It is only recently that arrangements have been made to train Africans as

¹ See Chap. IX, (*h*), p. 524.

² See Chap. XI, p. 681.

medical assistants.¹ The reason is perhaps to be found in the fact that much of the work for which the French are training Africans is done efficiently, as has already been mentioned, by European officials, both administrative and departmental, recruited in the grade of *agents territoriaux*.² The Belgians show a distrust, which is shared by some other governments, of the product of a purely literary education. It may be that this attitude is due in part to the influence of circumstances which have concentrated attention on the immediate needs of industrial and agricultural expansion; and it is noteworthy that the present Governor-General, M. Pierre Ryckmans,³ has pointed out that literacy can only create a claim to social superiority in an illiterate society, and that as soon as it ceases to be 'the privilege of a small *élite*' it will cease also to be the way of escape from the familiar environment.

(c) *The Language of Instruction*

The principle followed with regard to language is that the medium of instruction should be the vernacular, and that only those natives who are to live in close contact with Europeans should learn a European language; the only language which they should learn is French; this should be taught as a subject in the middle schools.⁴ It is, in fact, obligatory in these schools. Flemish, originally taught in some of the schools as one of the two official languages, has now been abandoned as a subject of instruction. There is at present no recognized *lingua franca*, as is only natural in so vast a territory. An adapted form of Swahili called Kingwana,⁵ somewhat different from the Swahili spoken in East Africa, is used as the medium in the Katanga schools, and in those of the Eastern Province, and appears to be making its way elsewhere; Lingala, Luba, and Kongo are also used over wide areas.

(d) *The Mandated Area of Ruanda-Urundi*

In Ruanda-Urundi the educational system follows that of the Congo in its wide use of religious bodies, who are here also predominantly Catholic, though the Concordat of 1906 does not

¹ See Chap. XVII, p. 1186.

² *La politique coloniale*, 1933, p. 104.

³ See Chap. III, p. 95.

⁴ See Chap. VI, p. 244.

⁵ E. de Jonghe, *op. cit.*, p. 88.

apply to the territory. Article 8 of the mandate, which follows generally the terms of the St. Germain Treaty, specifically accords to all religious bodies an equal right to erect religious buildings and open schools. There is evidence that there has been in Ruanda-Urundi the same difficulty arising from the competition of different denominations for school sites as has been seen in some of the British areas, and there was at one time a complaint that chiefs, who have the power of vetoing the grant of land for this purpose, had been influenced by their officers to exercise their powers to the prejudice of the Protestant missions. Local orders issued in 1936 were directed to impressing on the chiefs that there must be equality in this matter, subject to the standing rule that no mission can take up a site within two kilometres of another. There is the same general restriction of subsidies to 'national' bodies as prevails in the Congo; in Ruanda-Urundi, however, there is one Protestant mission which is qualified by the Belgian nationality of its personnel to receive the state aid. It is interesting to note the relative importance of the activity of the different denominations under these conditions. The Catholic primary schools had in 1935 a total of 29,671 pupils, or, including the *chapelles-écoles*, a rudimentary type of bush school, a total of 163,635; the Protestant primary schools had 2,695 pupils or, including bush schools, 19,300. Out of these totals, Catholic schools had subsidies for 29,471 pupils, and the Protestant missions for 5,645. There are some 530 pupils in schools maintained for Moslems.

Schools are classified in Ruanda-Urundi on the same system as in the Congo. An inspector of education is maintained by the state; but the only school classed as 'official', which is also the only one giving an education beyond the primary stage, is that at Astrida, which trains clerks, typists, and lower subordinates in the technical services. This school is under the charge of a Catholic body. The Nyanza school, which formerly gave instruction of the same nature under charge of an administrative official, has now been closed. The Astrida school also provides for the education of sons of chiefs, and the fact that the provision made for this class brings it under the control of a denominational body has attracted some comment by the Permanent Mandates Commission.¹

¹ *Minutes of the Thirtieth Session, 1936*, pp. 145 ff.

VII. THE PORTUGUESE COLONIES

In Portuguese East Africa there is a dual educational system for African and for European or Europeanized children. For the Africans there are primary schools of two grades followed by technical training. The lower primary course extends over three years and is officially described as a comprehensive course including the Portuguese language, geography of Portuguese territories, drawing, geometry, handwork and agriculture, physical training and hygiene, moral and civic education, and Portuguese songs. Portuguese is the normal medium of instruction. The vernacular may only be used in primary schools and then only for oral teaching. This ruling has been criticized by many missionaries, who found that children who had been taught to read and write in their own language were able to learn Portuguese more quickly than the others. In Mozambique three technical schools train tailors, shoemakers, carpenters, smiths, locksmiths, and typists, while one girls' technical school teaches sewing and domestic economy. These schools give a three years' course, which is stated to include higher primary education and apprenticeship to a trade. For children residing within 3 kilometres of a school, education is free and compulsory between the ages of 7 and 12 years. The official figures of school attendance do not distinguish between native and European schools. According to them, the state maintained 156 lower and 54 higher primary schools, with 12,345 and 4,131 pupils respectively, and missions maintained 254 lower grade schools with 36,918 pupils and 10 higher grade schools with 493 pupils; there were 2 'normal' schools for natives, with 72 pupils, and 42 technical schools with 1,676 pupils.¹ Until recently mission teaching was largely in the hands of Protestant non-Portuguese bodies, who established themselves in the territory in the middle of the nineteenth century and started numerous schools. The Catholics, after the collapse of their earlier efforts, did not come into the field until later. In 1935, however, an amendment was introduced to the Colonial Charter of 1933 providing that only Portuguese Catholic missions should receive state aid. It was felt that the Protestant missions, by effecting a breach in the religious homogeneity of the people and by their use of the vernacular in schools,

¹ The last official report on education in the colony was issued in 1931.

hindered the development of the Portuguese national spirit which it was desired to foster. One non-Portuguese body, the Swiss mission, has been able to meet the requirements of the law by establishing a consultative body in Lisbon and agreeing to recruit a fixed proportion of its missionaries from Portugal.

The European system includes primary schools and one secondary school at Lourenço Marques, giving courses identical with those in Portugal; an evening commercial course is attached to the secondary school. In 1935 the secondary school had 479 pupils, of whom three were African. Education is free and compulsory for children from 7 to 13 years. Training for service in government departments is open to children from the European primary schools: such training is organized by the Public Works, Medical, Printing, and Survey Departments.

In Angola the latest figures available (1930-1) give a total of 124 native schools with 6,537 pupils; of these 58 were managed by the state, 28 by Catholic, and 38 by Protestant missions. The Protestants experience the same difficulties there as in Moçambique, though before 1935 some of their schools received government subsidies. More attention appears to be given both by government and by missions to agricultural education in Angola than in Portuguese East Africa. European secondary education is more highly developed than in Moçambique; there is a big *lycée* in Loanda leading from the elementary school to the university, its final two years' course being similar to that given in American junior colleges.

VIII. GENERAL REVIEW

(a) *Principles Applicable to Native Education*

The review of educational systems in the preceding pages has been as far as possible objective; an attempt to discuss underlying principles will naturally raise more controversial issues.

In the opening paragraph of this chapter it was suggested that education in Africa should have a double function, namely, to provide the African with a better equipment for dealing with his own environment, and to prepare him for the changes to which that environment will in increasing measure be subject. It is clear that in the British areas in Africa attention at the outset was

concentrated so largely on the second of these two purposes as almost to exclude the first. The beginnings of education in Africa were laid in an age which assumed without question the intrinsic value of European civilization; African institutions were judged purely in terms of their resemblance to those already known, and concern for the improvement of African conditions manifested itself in the effort to make them approximate as closely as possible to those of Europe.¹ To many who held that view, the Christian religion was an essential element in the introduction of the African to civilization; hence the importance of mission schools, and the official encouragement given to missions. Present-day thought is not without reason critical of such an attitude to the problems of education. But in justice to our predecessors we ought not to forget that earlier policies were framed without the knowledge and experience that have since been gained. We ourselves can only ask of posterity that we should be judged by our efforts to comply with the most enlightened standards of our own time; examined by this test, the sincerity of purpose which animated many of the pioneers of African education is not open to question.

There were, of course, other less reputable influences at work. Many thought that if the African were to be allowed any introduction to European civilization, it should only be in the lowest grades of European industry. They insisted that education should be restricted to manual training and the minimum literacy necessary for a workman in European employment. This, however, cannot be treated as serious educational theory, and it is the efforts of those who were earnest in their attempt to civilize the African that must be examined. They concentrated their attention on providing literary courses, combined with the earliest and fullest possible instruction in a European language. Critics of African education, in speaking of the literary nature of a syllabus, frequently apply to the term a connotation which it does not justly bear; in this case, criticism must turn less on the literary character of the courses than on the fact that they attempted to engage the interest of the pupil in matters which lay outside the needs and experiences of African life. The history and geography which he was taught were often those of Europe; the teaching of literature tended to

¹ See the Privy Council Memorandum of 1847 referred to above, p. 1229, note 3.

confine itself to the grammar and syntax of a European language; there were at least some instances in which the pupil was taught the botany of European, not African plants. It cannot justly be argued that education of this kind conveyed no benefit whatever to the pupil. There must have been many to whom it gave a quicker intelligence and greater breadth of outlook, and school life, especially in the boarding-school, must have helped to produce habits of discipline and application. But it could not be said to be the type of education most adapted to help the African to make the best of his own environment. Some of the educational pioneers failed to realize that a type of instruction which might be suitable for the selected few designed for employment in teaching or in government service could not meet the needs of the population at large. In the second place, they did not recognize that even the education they were giving to the select few was not really adapted to the needs of men who, even if they were in clerical European employment, yet had to remain members of an African society.

As has been said before, the future which the early educationists envisaged was the development of the African on European lines, and they looked on education as the most potent influence for directing the process of evolution. To-day it will be generally agreed that it is not possible to forecast the precise direction which evolution will take, nor what type of social and cultural structure will eventually result. It will be determined by many influences, other than those which flow directly from administrative or educational policy; the introduction of a new economy, new methods of communication, and new occupations will equally have their effect, and the result will depend on the reaction of the African character to this complex of new influences. So far as deliberate policy can affect the issue, it is clear that in the interests of the African himself it should seek to moderate the pace of change, and allow full scope for the innate characteristics of the people to assert themselves in the conflict of forces that must ensue.¹

(b) Popular Education

Although in some respects education in British areas at the present day is by no means free from the burden of its earlier

¹ For a fuller discussion of this subject, see B. Malinowski, 'Native Education and Culture Contact', *International Review of Missions*, Oct. 1936, pp. 480-515.

traditions, there has been a significant change in the direction of policy. Emphasis is now laid on the first of the two purposes of education mentioned above, and attention is concentrated on the attempt to fit the African for dealing with his own environment. Many influences have contributed to this result. An age of positive values has been succeeded by one which recognizes that the worth of an institution must be judged in relation to the conditions in which it operates, and, as a necessary consequence, there is a growing appreciation of the need for sociological study of the reaction of primitive peoples to the introduction of new institutions. The general agreement that education cannot be confined to a few, but must progressively extend to the mass of the population, has focused attention on the problem of finding a suitable content for 'popular' instruction, which must bear a close relation to the realities of African life. The report of the Union Interdepartmental Committee on Native Education of 1935¹ is a significant mark of the change of South African opinion under the influence of this consideration. In the British colonies the new conception of the function of education seems to have been a consequence of the growth of the system of indirect rule, which is itself less a type of political institution than a philosophy based on an appreciation of the needs of native life. The new outlook found concrete expression in the memoranda of the Advisory Committee of the Colonial Office,² which have not only had their effect on government policy, but have served to give direction to the activities of missionary bodies. The result has been an increased use of the vernacular as a medium of instruction, the production of more text-books suited to African pupils, the introduction of agriculture and of manual training as part of the school course, the spread of teaching of the type associated with the Jeanes schools, and the substitution, at the secondary stage, of training of a vocational nature for literary instruction.

This policy of 'developing the African on his own lines', though in many ways an advance on earlier conditions, has nevertheless had its critics. There are Africans, particularly on the West Coast, who feel that an educational course which is designed to suit African conditions carries with it its own confession of inferiority.

¹ See above, pp. 1217, 1221.

² See above, pp. 1229-32.

There are, again, Europeans who feel that the policy ministers to the prejudices of those who, apprehensive of the economic competition of the native, would confine him to a separate world of thought and social habit. Neither objection can be lightly dismissed; in particular, no policy in education can succeed unless it carries the goodwill of Africans. But the objections appear to overlook the essential fact that the policy is not decisive of the whole course of African education; it applies only to that type of primary teaching which is given to the great mass of people who are predominantly rural in character.

The political philosophy underlying the French method makes it difficult to apply the same standards as have been used in examining the British. Education is the main instrument for carrying out the French policy of association, and it works through the dual system already described. This system is designed, on the one hand, to create an *élite*, inspired by French ideals of civilization, which will be fitted to take its part in the administrative life of the territory, and, on the other, to provide a popular form of instruction suited to the needs of the masses. The method chosen for the education of the *élite* is logically planned, and appears successful in attaining its purpose. The French pay greater regard to African conditions in their system of education for the masses: the rural school aims at improving the native as an agriculturist, and the urban school at assisting him to gain his livelihood in the towns. Through the fact that all education is free, equality of opportunity is secured, as it cannot be when the pupil's chances of completing his course depend upon his father's income. It is doubtful, however, if this dual system can be maintained in practice. The French political ideal prescribes the use of the French language as a universal medium of instruction. The use of French in the popular schools, and the interest in French culture which it stimulates, must tend to give the pupil an outlook which will differ only in degree from that of the *élite*. The whole trend of the French method is in effect towards the production of a civilization essentially non-African in character.

The Belgian system shows no such clearly marked tendencies. Its two distinctive features are a utilitarian outlook and a close association with religious teaching; the Catholic Church is mainly

responsible for education, and has a predominating influence in the majority of the schools. There is no planned effort to create an *élite*, and, wherever possible, the vernacular is used in the earlier stages of instruction; manual training is given a prominent place, and almost all post-primary education is vocational. It is necessary, however, to remember that the present educational system, like most other administrative institutions in the Belgian Congo, is a post-war creation, and the official Belgian attitude towards the introduction of the African to a European form of culture is not yet clearly determined.

The Portuguese educational policy, so far as its features can be distinguished, would seem to aim at Europeanizing the African; but it does not at present display the same force or directness as the French system, and it is perhaps unlikely that it will in the future. In any case, the conception of a 'European' form of civilization would hardly be the same in the Portuguese as in the French colonies:

The trend of educational theory noted in the British areas is clearly marked, but it has not yet acquired that systematic character which is so marked a feature of French policy. True, there is always value in elasticity of method, and systematization is often most successful when it waits on experience instead of following a rigid logic, but the fact remains that the British colonial governments have placed widely different and indeed inconsistent interpretations upon the policy indicated in the memoranda of the Colonial Office Committee. It has been suggested that to remedy this defect should be one of the first of British aims. The inequality of expenditure in different areas is striking. It is not merely a question of increased financial provision, though that will obviously be necessary. The Commission on Higher Education in East Africa¹ recommended that an extra £50,000 per annum should be spent on primary, secondary, and vocational education in Uganda alone, quite apart from the money necessary for the proposed development of the Higher College.

If the policy is to be fully applied, the state will have to assume greater responsibility for education, and direct more systematically the syllabus of instruction, in association with the advisory

¹ *Report*, op. cit., Colonial 142, 1937, p. 116.

bodies which it has created. In approaching this task the administrations will encounter many problems which still require solution. It may well be felt, for example, that the time has arrived when the state should show greater discrimination in the support it gives to the smaller mission schools. It is true that the value of education lies as much in the formation of character as in the quickening of intelligence, and true also that religion is an important factor in the formation of character. But religious instruction, more than any other type of teaching, demands understanding and personality on the part of the teacher if it is to exercise any permanent influence, and it cannot be claimed that the small bush school, with ill-trained staff and irregular attendance, has any more value for character training than for giving instruction. An effort should also be made to eliminate wastage. At present, a large number of primary schools are clogged with older children who have failed to make progress and are unlikely to do so. Some system of superannuation would seem to be indicated. Another problem is the difficulty of assigning to literary and manual instruction their due place in 'popular' education. It is not now questioned that popular education must contain an element of literary instruction, though it is argued that its content must be related as far as possible to African needs and experiences. Manual work can, under suitable conditions, have an educative influence, but its utilitarian value is limited, for it is doubtful if, in the short period which general education covers, it can be more than a preliminary to instruction in a craft or trade. There is, again, the question whether the primary stage of education should be complete in itself, or designed to afford a preparation for a more advanced course. There would appear to be a growing agreement, save in some parts of West Africa, that since the majority of pupils can scarcely complete even the primary stage, the instruction given at that stage should be as far as possible complete in itself; experience shows that this is not incompatible with the provision of a ladder by which selected students can proceed to higher courses either of vocational or other training.

But here there is a practical issue involved. Popular education, if complete in itself, cannot provide a sufficient period of instruction in a European language to give the pupil an adequate know-

ledge. The recognition of this fact inevitably produces a demand for a further course, and the popular course tends to assume the character of a preparation. This in turn reacts on the whole syllabus of popular education.

The place to be given to the vernacular, or alternatively to a European language, in popular education, is thus a crucial problem. There can be no question of the value of the vernacular as the easiest approach to the mind of the pupil, and therefore it is clearly the best medium of instruction at the earliest stage, and is in practice widely used at that stage. But the recognition of this fact still leaves for decision the question whether, as soon as the initial stage has been surmounted, further study should be conducted in a vernacular or a European language. The matter has already been dealt with, and some of the difficulties involved are further illustrated in a previous chapter.¹ Discussions on this question show a marked difference of view regarding the answer to be given. There is little disposition on any side to question the general proposition that the language of a people is an essential part of their life, and is for them the most effective instrument of thought; the division of opinion arises over the implications of this principle. There is in the first place the practical objection that we cannot treat every tribe as a people or every dialect as a language; apart from the obvious difficulty of finding adequate teachers for the numerous dialects involved, many of which have as yet no script, we should be in danger of creating barriers to that intercommunication of thought which is essential to intellectual progress. The attempt to meet this difficulty by the use of a *lingua franca* or a 'union' language is open to the argument that we thereby create an artificial medium which is alien to the people, though admittedly less so than a European language. The French would add that it is a waste of effort to teach Africans to read in a language that has no literature, and then write books for them ourselves to satisfy the new demand for reading matter. There are, in the second place, those who feel that it is not possible to disregard the strong desire shown by many Africans for a knowledge of English, not only for its use as a medium of approach to the administration, and in commercial and industrial relations, but as

¹ Chap. III.

a symbol of a higher status; experience elsewhere shows that this represents a force which is capable in the long run of prevailing over any determination at which educational authorities may arrive. There are, thirdly, those who urge that even the most convinced advocates of the vernacular do not suggest that higher education can for the present be conducted in any of the African languages. They conclude that, on all these grounds, the claims of English as a medium of instruction must outweigh those of any of the vernaculars.

In seeking a conclusion it is inadvisable to assume that any course now adopted must necessarily represent a final policy; educational procedure must adapt itself to changing circumstances, and not the least of these will be the change in outlook of Africans themselves. Not only is a final decision impracticable, but local differences may reasonably be felt to be such as to make any uniform solution impossible. There are conditions, such as those of the urban and some other areas in South Africa, in which native life is so closely bound up with a dominant white civilization, that the native is not adequately equipped to meet the conditions with which he has to contend unless he knows a European language. There are some areas in West Africa where conditions point to the same conclusion; with every desire to assist the African to retain an interest in his own institutions, it must be realized that Africans in this area are not likely to accept as sufficient any course of instruction which does not give them teaching in English. Indeed, it is a significant feature of African opinion on the West Coast that even a local provision for education up to university standard is viewed with suspicion, as an inferior alternative to facilities for study at British institutions. Elsewhere the balance of argument appears to incline in favour of the use of the vernacular; but the whole question is one which, alike in its importance and complexity, seems to require that the administrations should seek the fullest collaboration of sociological inquirers in considering the consequences involved.

(c) The Payment of Fees

In French territories, where, as we have seen, education forms part of a policy of political and economic development, education is

free, but the authorities limit the numbers of pupils who are allowed to attend the higher courses. In British areas the usual policy is to charge fees, and in government and missionary boarding-schools, such as those at Fort Hare, Achimota, Budo, Makerere, and elsewhere, charges are made which, in the absence of bursaries or exemptions, would preclude any but the more well-to-do Africans from attending the courses. Thus annual fees in Uganda boarding-schools vary from about £3 to more than £20; in the Tanganyika boarding-school fees are £3; in the Gold Coast in ordinary schools they vary from £2 to £6, but at Achimota they amount to £33, exclusive of the cost of school books; at Fort Hare they are £10, or a fifth of the actual cost of board and schooling. In primary and bush day schools small fees are the rule, and may consist of small contributions of food towards the maintenance of the teacher or small sums such as 3d. a school term. Where local levies exist to provide native administration schools, fees do not appear to be charged, but in the Northern Provinces of Nigeria, where most of the cost of education is met from the native treasuries,¹ fees are charged and paid into the treasuries. In 1936 they amounted to 6 per cent. of the cost. In Northern Rhodesia it is said that the imposition of small school fees and payment for school books counteracts irregularity in attendance, which otherwise is prevalent. It has to be remembered that, except in the form of experiments in limited areas,² compulsory education does not exist, and as children assist their parents in the house and garden they are not willingly spared for long periods. On the other hand, it is objected that the payment of fees often precludes comparatively poor chiefs and headmen from sending their children to boarding-schools, while wealthy salaried employees find no difficulty in meeting the expense, and thus, in some areas, the educated class may be inadequately represented among the ruling families.

The question of payment of fees is of considerable importance in connexion with comparatively expensive higher education, and if the best pupils are to be brought forward for training for the public services, or for service in the native administrations, bursaries or scholarships, or grants from government or local funds,

¹ See above, p. 1233.

² See Nyasaland, *Report of the Education Department*, 1936, p. 20.

would appear to be necessary, to cover not only board and school fees but also travelling. Alternatively, where various governments make grants towards the maintenance of a centre for higher training, such as that of Makerere, it will presumably be for each contributor to decide how much will be demanded in fees from the candidates from its area.

(d) *Higher Education*

The considerations which decide the character of higher education are largely political, for the type of instruction given depends on the view held of the place in society which the educated African may be expected to fill. As has more than once been remarked, the French look on the more highly educated African as a member of an *élite* whose specialized training fits him to assist the administration in carrying out its own ideals of civilization. By limiting themselves to this objective, the French have clearly defined the educational issue, and have evolved a system well adapted to its purpose. At present, the educated French West African takes an important but usually subordinate part in the administration.¹ Though persons of African origin are represented in the colonial administrative cadre, the majority come from West Indian colonies, and have qualified for service by completing their education in France.² That West Africans are not yet represented in any number is due to the fact that on passing out of the local professional schools they have been at once absorbed into the specific employment for which they have been trained. French policy has not favoured the appearance of the educated African at the local Bar; in the absence of a legislature he has not the political opportunities which are open in the British Gold Coast or Nigeria, nor has he attained the same importance in journalism. On the other hand, the absence of colour prejudice makes it possible for the educated African to live in some considerable measure on equal terms with the Frenchman, and the colonial aspirant can hope also to secure a place in the activities of the mother country.

British policy as yet exhibits no clear view of the future of the

¹ See Chap. VI, pp. 237, 239, 241.

² It may be remarked, however, that an African, M. Eboué, is Secretary of the French Sudan, and from time to time acts as Governor.

educated African. Though, as has been shown, there has of recent years been a movement in favour of vocational rather than general education, it has not been carried to the length of confining education to vocational courses or restricting the number of those entitled to receive them. At the present stage in the evolution of educational policy, it is of importance to know what position it is intended to assign to the African in the service of the administration. On this point, however, there has been no declaration of general policy. There have been some expressions of opinion by local authorities on the subject, as, for instance, that all posts in government service, except those of political officers and judges, are in future to be open to Africans who have reached the required standard of education, or that, on grounds of both justice and economy,¹ the general interest requires that there should be a progressive substitution of an African for a European establishment. That no principle of general application has been formulated by the Colonial Office is not, as has sometimes been suggested, due only to the difficulty of forecasting the precise form of the political and administrative structure which will be evolved under the influence of the theory of indirect rule. There are few instances in British colonial history when the future of the educated native has been consciously determined, or the educational system deliberately adjusted to fit him for it. Accepting the general value of an education based on the European model, British governments have been content to wait until the product of that type of education has asserted his claim to a position in the political or administrative life of the country; when the position has been finally accorded it is more often in recognition of a claim which has been tacitly encouraged than as a result of a predetermined plan. It may be justifiable to conclude that for some time at least it is unlikely that British administrations in Africa will commit themselves to a definite view of the future of the educated African and give a decisive direction to the educational system. The effect of the report of the Commission on Higher Education in East Africa remains to be seen. That Commission recommended a generous education policy, emphasizing the fact that there is little danger of creating

¹ Address by the Governor to the Legislative Council, Gold Coast, 1926.

a class of educated unemployed, as there is a growing need in Africa for the services of educated Africans. It was, however, strongly impressed with the need for a practical outlook on educational policy. 'The primary need of East Africa', it said, 'is the use of her soil';¹ and again, 'The main purpose of the East African governments in education . . . must for the present be the improvement of agriculture, animal husbandry, and health.'² For the present, therefore, there is likely to be an increasing emphasis on the vocational character of higher instruction, on grounds of expediency if not of general principle.³ The relative part to be played by types of instruction which seek to meet existing demands for specific knowledge, and those which are more concerned to create a philosophy of life, must await a decision as to the degree of responsibility which it is intended ultimately to give to the African in the management of his own affairs. It is, finally, clear that all higher or professional training will be carried on in English; it will be many years before the African is likely to initiate a movement similar to that now seen in India, for the use of the vernacular as a medium in higher education.⁴

(e) *Native Art and Music in Education*

An educational problem which deserves more study and discussion than are possible in connexion with the present Survey is that of the teaching of art and music in native schools. Indigenous African arts and music are primarily functional: the African artistic genius has produced objects of singular beauty inspired by religious beliefs and social customs and the necessities of social and domestic life. These sources of inspiration are profoundly modified, if not destroyed,⁵ by modern conditions, and there is evidence of a decline in artistic taste, accelerated by the replacement of indigenous articles by those of European manufacture, the commercial exploitation of so-called native crafts, and lack of encouragement. In this connexion the efforts made at Achimota, where teacher-training pupils are taught carving by African

¹ *Report*, op. cit., Colonial 142, p. 14.

³ See, for instance, the speech of the Governor of Tanganyika quoted in *Report to the League of Nations on Tanganyika Territory*, 1937, p. 195.

⁴ All teaching in the Usmania University, Hyderabad, is now carried on in Hindustani.

⁵ D. Westermann, *The African To-day*, 1934, p. 100.

instructors, using as far as possible African tools,¹ are of particular interest, and are said to demonstrate that the peculiar characteristics of the African artistic genius persist in whatever form of art is found most suitable.² It seems that the teaching of a type of handwork, closely related to the traditional crafts and forms of art, in lower as well as more advanced schools, assists in preserving and developing traditional standards of taste. Difficulties may be experienced in musical training owing to mission influence, which favours European tunes, and owing to the changes in the social customs by which indigenous music was inspired.³ An extensive survey of native music has been made by Professor P. R. Kirby.⁴ He considers that the teaching of music in native schools can be improved by a study of African systems of harmony, and cites the apparently successful experiments carried out by the Rev. A. M. Jones at Fiwila, in Northern Rhodesia, in the use of new tunes adapted to the rhythm of the local vernacular.

IX. CULTURAL AGENCIES

(a) *The Communication of Ideas*

Education in Africa, as has already been suggested, consists not so much in handing on to a new generation accumulated stores of knowledge and experience, as in helping the African to adapt himself to a new and rapidly changing world. The phenomenon of rapid change is not confined to Africa, but in other continents, where the gulf to be bridged is far less wide, discomfort and disturbance have been reduced by means of highly developed machinery for the spread of new ideas and information. The press has played its part in popularizing scientific discoveries, political ideas, and new knowledge regarding social customs. Broadcasting tends to familiarize an immense public with points of view and information hitherto unfamiliar to them; and when it is used consciously as an aid to education, scholastic or civic, or to political propaganda, its persuasive effect is perhaps greater than that of any other agency.

¹ *Report on Achimota College*, 1934, p. 16.

² *Arts of West Africa* (ed. M. E. Sadler), 1935, p. 15.

³ P. R. Kirby, 'The Effect of Western Civilization on Bantu Music', *Western Civilization and the Natives of South Africa* (ed. I. Schapera), 1934, pp. 131 ff.

⁴ For a list of his publications see *The Bantu-Speaking Tribes of South Africa*, 1937 (ed. I. Schapera), pp. 441-2.

The cinema has also played a large, though not invariably a beneficent, part in moulding social ideas.

In Africa, over the greater part of the continent, these agencies scarcely exist; but in view of the importance which attaches to the printed word, the broadcast word, and the moving picture as instruments of political and social change, some estimate of the extent to which they are available to assist Africans to adapt themselves to new conditions cannot be omitted from this Survey.¹

It is convenient to draw a distinction between two types of communication. Books and newspapers circulate directly only among literate populations, though literates frequently read to illiterates. Print has therefore a limited though an extremely important public. Broadcasting and films can make direct contact with people who cannot read. It has been suggested elsewhere that these agencies are likely to make a more direct appeal to partially educated than to totally uneducated people.² While this may be so, it is true that Africa has, as will subsequently be shown, only a limited experience of their use, and it is not possible to speak with confidence of the extent of the influence which they may be able to exercise.

(b) *Books and Newspapers*

European. The supply of books for Europeans in Africa presents special problems. The official, trader, or missionary, cut off for long periods from normal intellectual stimulus, may suffer for lack of adequate reading matter. The growing place of library services in western countries, both for general and for special use, has helped to direct attention to the inadequate facilities in African colonial territories. In the Union, libraries, municipal or university, have grown up in European centres on the usual lines. In 1929 the Carnegie Corporation of New York published two memoranda on libraries in the Union, Rhodesia, and Kenya, covering European and non-European readers. They subsequently gave grants for the establishment of a central library in Pretoria, as well as for developments in the other territories covered by their

¹ C. C. F. Dundas, *Means of Spreading Thought among the Natives*, and H. Jelgerhuis-Swildens, *Les moyens modernes de la diffusion de la pensée dans les colonies*, Institut Colonial International, 1936.

² See Chap. XVI, p. 1110, and Chap. XVII, p. 1199.

inquiry. A children's library has been opened in Nairobi, and a central students' library is under consideration. Some library facilities exist in most British territories, though often official or technical in character, and many missions maintain small European libraries. The beginnings of a library in Africa for Belgian Congo officials go back to 1898, and administrative libraries were established by a decree of 1910. In 1931 a further decree authorized the Governor-General of the colony to set up public libraries: these are managed by commissions consisting of officials and an equal number of readers' representatives. There are now some twenty-three public libraries in the Belgian Congo and Ruanda-Urundi, though, as a result of economic stringency, a government subsidy is available for Léopoldville only. There are also mission libraries and libraries attached to technical departments of government.¹ A similar interest in European libraries is developing in French territories in Africa,² and provision is being made for the institution of a library at Dakar.

African. The demand for European books among Africans ranges from the professional man in Lagos with a well-stocked private library to the child or adult who requires the simplest reader. Both mission and secular presses, at home and in Africa, now issue a considerable number of books in European languages specially prepared for African readers. These are mainly devotional or educational in character, and in many of them one of the varieties of simplified English is used. 'Basic English' is framed on a selection of 850 scientifically selected 'basic' words which, it is claimed, cover all the essential 'operative words' and 'directions', all synonyms being excluded.³ Further words can be added to enrich this minimum and to include words both of universal and of local usage. Other systems are based on word-frequency counts, and use graded vocabularies beginning with 1,000 words.⁴ An inquiry financed by the Carnegie Corporation of New York⁵ devoted two years' study to the problem of simplified English, and

further research is being undertaken by the Institute of Education in London.

Apart from educational books, there is a growing African public for general reading; it is said that there is a sale for the books of Edgar Wallace among the Gold Coast African police, and that *Little Women* and *A Tale of Two Cities* are read by Nigerian school-girls. African authors who wish to reach an audience beyond their own language group necessarily use European languages. The *Prix Goncourt* was won in 1921 by René Maran, a native of French West Africa, and a substantial number of Africans have published books in English. Libraries for Africans are still in the elementary stages. Some of the grants made by the Carnegie Corporation of New York were given for setting up circulating libraries in schools and other centres south of the Zambesi. Some Departments of Education are experimenting with teachers' libraries. The University of the Witwatersrand has a non-European reading-room and reading circle. In West Africa the library of Achimota College is made available for old students, and individual Africans are initiating small circulating libraries. One native treasury in Southern Nigeria has granted funds for a local library. A stage seems to have been reached in which co-operation between different agencies and neighbouring territories would yield valuable results. At present, few facilities exist for the sale of government publications in territories outside the territories of origin, though they frequently deal with matters of common interest.¹

The larger problem of books for Africa, however, concerns the provision of reading matter in the many languages and dialects of the continent.² Over large areas the demand for books and newspapers in native languages is considerable. This was recognized by the Protestant missionary societies when in 1929 they set up an International Committee on Christian Literature for Africa, on which Bible societies, religious publishing houses, and other similar bodies were represented. It was found that only some 250 of the languages of the continent were provided with written material. The Bible, the most widely read book in Africa, already

¹ 'Books for Africa', *Quarterly Bulletin of the International Committee for Christian Literature for Africa*, vol. vii, no. 2, 1937.

² See Chap. III, pp. 68-70.

exists in about 240 languages, but schoolbooks are still poorly represented in many language areas, and for post-school reading the provision is poorer still. There appears to be an unsatisfied demand for simple books on health, and for explanation of government and its agencies. The International Institute of African Languages and Cultures has done much to encourage the writing of books by Africans in their own languages, by offering prizes for manuscripts and by assisting in their publication.¹

The vernacular press is beginning to play an important part in some areas of British Africa.² In the Union some fifteen native papers circulate, the *Bantu World* in six languages. A vernacular paper is published by the Transkei General Council. In Southern Rhodesia the *Native Mirror*, with a circulation of some 3,500, appears in three languages, and its distribution is assisted by the Native Affairs Department. In Northern Rhodesia a government newspaper, *Mutende*, with articles in English and in several vernaculars, represents an interesting experiment in securing native co-operation and interest. The Tanganyika Government has produced *Mambo Leo*, a native monthly journal in Swahili, with an African secretary. This paper, which circulates through East Africa, contains lively correspondence pages and is much read aloud in villages. Its rising circulation has now passed 14,000. The Tanganyika Education Department also publishes a journal, *Mwanafunzi*, for schoolchildren. In Kenya a government organ, *Habari*, was given up for financial reasons, but there is a vernacular paper produced by the Kikuyu Central Association. In the remaining British territories of East and Central Africa the native journals are mainly missionary. In West Africa, besides the many African-owned newspapers in English, the *Northern Province News* in English, Hausa, and Arabic is an official organ.

In French Equatorial Africa there is no native press, though occasional articles are contributed by natives of the territory. French West Africa is more liberally supplied, with an Arab weekly in Dakar, and a variety of small-circulation journals in French and in the vernacular, in which educated Africans take part. In the Belgian Congo native papers in local vernaculars are published by the missions and are mainly religious. In Angola

¹ See Chap. III, p. 69.

² Ibid.

and Moçambique likewise there are vernacular mission papers both daily and weekly.

The production, distribution, and storage of books in Africa present peculiar difficulties. Cost makes vernacular publication a non-commercial business when the buying public is very poor. Mission bookshops, caravans, and book dépôts run by Africans assist in distribution, but for reaching a wider public it has been suggested that bookstalls in African markets might be developed, and boxes of books at village schools. Damp, white ants, and other pests are often destructive of books and paper. Nevertheless, in view of the immediate and urgent need for the wide dissemination of the elementary facts of hygiene and better living generally, every effort to spread the use of the printed word is valuable. An example of the way in which illiterates may be reached by books was the formation of vernacular reading circles in Tanganyika. These were managed by volunteer native readers; in one case the readings were attended by over a hundred listeners; in another the listeners increased to 300 and had to be divided into three groups, and the interest aroused led to a demand for evening reading-classes for adults.¹ From such rural listeners at one end of the scale to the small but important groups of educated Africans in urban areas at the other, books are essential to the spread of information and the development of public opinion, and, since literacy is steadily increasing, it would be regrettable if the supply of literature were to remain inadequate.

(c) *Broadcasting*

Wireless communication has already provided valuable links for Europeans in Africa with their home countries and with the outside world in general, through the development of European short-wave stations catering, indeed competing, for the ears of overseas communities. Since Sir John Reith's report on Broadcasting Policy and Development in the Union of South Africa² resulted in the establishment in 1936 of the South African Broadcasting Corporation on lines analogous to those of the British Broadcasting

¹ A. T. and G. M. Culwick, 'Social Propaganda in Illiterate Africa', *Oversea Education*, vol. viii, no. 5, 1938.

² Sir J. C. W. Reith, *Report on Broadcasting Policy and Development*, U.G. 18, 1935.

Corporation, the service, which had begun on a commercial basis as early as 1924, received a fresh impetus, and programmes, both cultural and recreational, have since been considerably developed. The necessity for a bilingual service in English and in Afrikaans in parts of the Union adds greatly to the difficulty of programme building; in spite of this there were in 1937 over 160,000 licences, varying in cost from 35s. per annum for listeners near a main station to 10s. for those at greater distances. The Corporation operates three main stations and three relay stations, together with two experimental short-wave stations. A proposal is under consideration to take over a military short-wave station, to be operated from Pretoria, as one of the most powerful short-wave transmitters in the world. This scheme, if put into effect, would provide a link with the whole continent.

Experience in India¹ has shown that advice and instruction can successfully be given to certain types of illiterate people by means of wireless programmes, if these are used with full understanding of the medium as well as of the audience; among people of some measure of education it is possible to accept broadcasting as a recognized medium of instruction and culture, whatever its other potentialities for good or ill may be.² Its use by administrations would make it possible to communicate a larger amount of new information at first hand, instead of through second- and third-hand agents of doubtful reliability. Its capacity to suggest the living personality behind a voice gives it an advantage over printed instructions, even where these can be read, and would enable officers to maintain continuous contact with the people of their villages. Such developments have up to the present been hampered by financial considerations, as well as by technical problems such as the availability of wave-lengths and atmospheric conditions.

In February 1936 a committee was appointed by the Secretary of State for the Colonies to consider and recommend what steps could usefully be taken to accelerate the provision of broadcasting services in the Colonial Empire, to co-ordinate such services with

¹ 'Broadcasting in India', *The Times*, July 27 and 28, 1937.

² *School Broadcasting*, and *The Educational Rôle of Broadcasting*, League of Nations, International Committee for Intellectual Co-operation, 1933, 1935; H. Matheson, *Broadcasting*, 1933.

the work of the British Broadcasting Corporation, and to make them a more effective instrument for promoting both local and imperial interests. In their interim report,¹ published in 1937, the committee paid tribute to the value of the empire service, and to the usefulness of local broadcasting systems capable of relaying it, as well as of providing local programmes. They observed that no dependency could be expected to incur substantial and permanent loss on the equipment and maintenance of a broadcasting system designed solely or mainly for entertainment, though it would be justified as an instrument of administration and education. They examined in turn the possibilities of local wire broadcasting and of local wireless broadcasting, and noted that these were not mutually exclusive. In regard to the former, a circular dispatch was sent out by the Secretary of State in May 1935. With a small capital outlay, and a central receiving set capable of giving good reception of empire programmes, subscribers in a closely populated area can receive both overseas and local material at a cost of about £3 per annum, including hire of loud-speaker, and with no technical trouble to themselves. It is possible, moreover, to run feeder lines to sub-stations, as, for example, in the Gold Coast, where lines are run from central relay stations at Accra and Sekondi to Achimota and Takoradi respectively. Moreover, where telephone lines of sufficiently high quality exist, it may sometimes be possible to use them as a means of reaching remote areas.

Wireless broadcasting is, however, the only method of effectively covering a whole territory. It entails a heavy capital outlay and probably in the early years substantial recurring loss, though it might be possible to reduce this to some extent by the part-time use of radio-telephone transmitters. The committee found that 'at least some expenditure is demanded of colonial governments by way of experiment and investigation', and they recognized that if broadcasting is used by such governments for administrative and educational purposes, this carries with it the obligation to assume responsibility for reception sets and the supervision of listening centres. In order to assist governments to decide on future developments with expert assistance, the committee pre-

¹ *Broadcasting Services in the Colonies*, Colonial 139, 1937.

pared a questionnaire, relating both to technical and to programme problems, for circulation to colonial governments.

Local broadcasting services appear to have made more progress in British than in non-British territories. In Kenya European interest and enterprise have been responsible for a station at Nairobi now operated by Cable and Wireless, Ltd., which uses both medium and short wave-lengths and transmits both local and empire programmes; an experiment from this station is under consideration for special broadcast programmes in English and the vernacular to African listeners in the Kiambu native reserve, supervised by a committee representing the health, agricultural, and other services. Loud-speakers would be installed at district headquarters, and other centres such as bush schools, markets, or hospitals.

Sierra Leone, the Gold Coast, and Nigeria have established stations for the reception and re-transmission by wire broadcasting of empire programmes, as well as of local material. In Nigeria a radio distribution service has been established at Lagos for subscribers. The use of this system as a means of spreading elementary information about market-prices, control of pests and diseases, and other matters is under consideration by the Agricultural Department. In the Gold Coast a relay exchange of 2,000 subscribers, 80 per cent. of whom are Africans, exists at Accra. A weekly newsletter is broadcast from this station to other centres in the colony. Provision is being made for the extension of the broadcasting service to ten new centres. One of these was included at the request of a chief, the Omanhene of Winneba; another results from an agreement between the government and the Consolidated African Selection Trust, Ltd., whereby a re-diffusion service will operate at the company's mining camp at Akwatia. The company guarantees an annual payment of £350 in return for equipment and sixty loud-speakers, and makes available servicing assistance for the maintenance of power plant, both at Akwatia and at neighbouring villages which may subsequently be linked by wire. The training of Africans in broadcasting work has been attended with success, and it has been found possible to staff stations with Africans.

Broadcasting shows signs of development in French, Belgian, and Portuguese territories, both for official purposes and for listening to home programmes. The question of instructional broadcasting

from Dakar and Bamako is under consideration. The Radio Club at Brazzaville has established a small local broadcasting station on a wave-length of 24 metres.

Further local experiment appears to be needed in order to discover the most effective and economical methods of using broadcasting as an aid to education and improved contact between administrations and peoples. Experience has already shown that Africans take readily to wireless apparatus, and are capable of taking charge of it. It would seem to be of great importance that the results of all experiments in vernacular broadcasting, based on village or communal listening, should as far as possible be pooled and made available to all concerned; experiments in India, Palestine, and elsewhere may be no less worth studying for African purposes. Moreover, if broadcasting is to become an integral part of administrative machinery, it may be necessary to reconsider expenditure on normal services which involve propaganda and education, in order to make the most economical use of all available methods.

(d) *The Cinema*

In the cities and towns of the Union, and in similar communities elsewhere, cinemas have sprung up, as they have sprung up in urban centres all over the world, and are supplied with films which, as elsewhere, originate to an overwhelming degree in the United States of America. These present for the white community the same problems which the cinema presents elsewhere.¹ In the Union, censorship provisions were put into force by an Act passed in 1931, covering the subject-matter and display of films for the general public. The cinema of the European creates special problems in its effects upon the African,² similar to those created in India and other parts of the world where two cultures meet. Although varying degrees of censorship exist, and, in areas where there is a colour bar, Africans are not admitted to European cinemas, few suitable films are as yet available for African audiences.

In 1929 the Colonial Films Committee appointed by the then Secretary of State, Mr. Amery, examined the supply of suitable

¹ *The Film in National Life*, Commission on Educational and Cultural Films, 1932.

² H. Jelgerhuis-Swildens, op. cit.; G. L. Latham, *Means of Spreading Thought among the Natives*, Institut Colonial International, 1936.

films of entertainment, educational, or cultural value.¹ They accepted the view of the trade representatives that a supply of general films could best be secured through trade channels, and urged British film companies to turn their attention to the colonial market. Their recommendations included the setting up by the Film Group of the Federation of British Industries of a board, having the assistance of an advisory committee appointed by the government departments concerned, which should select films from those submitted and be responsible for distributing them through the appointed agents for each territory. It was believed that a substantial supply of films suitable for educational work already existed, and the committee recommended the appointment of an officer from the Colonial Education Service to undertake, in collaboration with the technical advisers of the Colonial Office, the tabulating of such films, and to keep colonial governments informed, as well as to receive from them particulars about the types of films required. The commercial organization suggested for the supply of general films could, it was thought, undertake also the distribution of educational films.

The Committee believed that the problem of censorship could be adequately dealt with by local boards with substantial powers and status. But it was urged that in tropical Africa the necessity of preventing the more demoralizing western films from reaching African audiences was so great, that local action would require the support of a strong central board in London. It was recommended that quota facilities should be given to cultural films, that all cinematograph displays should be regulated, as well as posters of films, and that local safeguards should be taken against the making of unsuitable films in Africa, or the performance of dangerous acts for film purposes.

The Committee's suggestions have been almost wholly without result. Their expectations that the British film industry would meet the needs of the colonies or develop the colonial market proved unduly optimistic. In view of the poor commercial return it was indeed unlikely that the British film industry, faced with difficulties at home, could have embarked upon colonial activity, and in the light of experience subsequently gained, it is improbable

¹ Cmd. 3630, 1930.

that they possessed enough knowledge of colonial needs to produce acceptable films. The appointment of an officer of the Education Service to centralize and distribute information about suitable films was not proceeded with, and no central censorship committee was established in London. It is true, however, that local boards have been set up by ordinance in all British colonial dependencies in which no provisions for censorship already existed. The personnel of the committees varies from small groups of official members, to larger groups including missionaries, wives of officials, local residents, &c. Their responsibilities cover the display of all posters as well as of all films, and include the right to cut as well as to ban or license. In most territories permission is also required before films may be made, as a precaution against the filming of unsuitable subjects or of scenes involving danger to life. Notwithstanding the lack of outside interest, considerable use of the cinema for educational and instructional purposes has been made through the local enterprise of administrative, educational, and technical departments in Africa. In Nigeria, for example, a fully equipped lorry for health propaganda purposes has been obtained by means of a grant from the Colonial Development Fund. The greater part of the money is being spent on the local production of films and on the upkeep of apparatus.

In 1933 the Department of Social and Industrial Research of the International Missionary Council, recognizing the few facilities for recreation which civilization was leaving to the African, and the widening gap in outlook between industrialized workers and their rural background, considered the possibility of research in the production of cultural films. This project was eventually launched as the Bantu Educational Kinema Experiment.¹ It was financed in the first instance by the Carnegie Corporation of New York, and was carried out with the co-operation of the British Colonial Office, the East African governments, the British Film Institute, the International Institute of African Languages and Cultures, and others. The report,² published in 1937, describes the thirty-five films made on the spot, with Africans as performers, and commentaries in several vernaculars. It outlines a scheme, with costs, for local film-

¹ See Chap. XVI, p. 1110.

² L. A. Notcutt and G. C. Latham, *The African and the Cinema*, 1937.

production units, sound-recording units, and one central organization in London to serve all territories concerned in the Empire. A group of six East African territories would, it was expected, secure some 70,000 feet of 16-millimetre film annually, at a total cost of £5,200 capital expenditure, and an annual recurring cost of £14,300. It is believed, however, that within a few years such a scheme would be almost self-supporting.

The experiment demonstrated the ability of the African both to act for films and to appreciate them when made, even to the extent of paying to see them. It taught the staff concerned that suitable subject-matter, conceived as far as possible from the African's standpoint, was more important than technical excellence, and that it was possible to demonstrate new methods of health and agriculture by means of films. The report shows also the opening awaiting entertainment films designed for a new African public. At the same time, the need for further research and experiment to discover more precisely the types of films wanted, and the ideas which certain scenes or stories suggest to African as distinct from European minds, was made apparent. In this connexion it may be noted that an experiment in Tanganyika is now being considered by an Administrative Officer and an artist, to study the reaction of village Africans to simple pictures; it is, for example, by no means certain that illustrations in school books, as well as still or moving pictures, always convey the ideas or the morals intended by those who display them.

In South Africa a Film Division of the National Bureau of Educational and Social Research was inaugurated in October 1936. A Film Advisory Board was at the same time established by the Minister of Education, representing fifty appropriate organizations and interests. The use of the cinema as a means of interpreting European civilization to Africans is one of the subjects with which the Board is concerned.

Although North Africa is outside the scope of this Survey, it is worth noting that in Algiers the Post Office is used as a distributing agency for films from a central film library, providing both educational and recreational films. The French government has encouraged local notables to provide cinematograph outfits and has afforded some help in certain cases.

In French West Africa and in French Equatorial Africa the cinema is naturally less developed. Regulations have been in force since 1934 for the control, through local commissions analogous to those in British territories, of film displays and of the making of films. Commercial films reach a considerable public in French West Africa, and admission to cinemas is open to all. A beginning has been made with educational films, especially in connexion with the campaign against sleeping sickness. In the Belgian Congo the system of control in force is similar to that in the French territories.

The use of cultural agencies in the education of adult Africans suggests a wider problem in British territories. In the more advanced areas, especially in West Africa, groups of educated Africans are showing the first signs of nationalist feeling, and there is evidence in journalistic and political activities of a strain of bitterness due, perhaps, to the apparent contradiction between our political liberalism and our social exclusiveness. The groups may at present be small, but their influence is one which may increase considerably with the advance of education. Social contact, which might do much to counteract ill-informed criticism and undesirable influences, hardly exists in territories where relations between the races, however friendly, are mainly official or that of employer and employee. The French have been more successful not only in spreading knowledge among the metropolitan population of the arts and cultures of their African dependencies, but also in associating educated Africans with French aims; their methods, involving direct government action, may be unsuited to British ideas, but the provision of facilities in British territories for the study of British political and social aims, and for the exchange of ideas between the two races, is a matter which appears to need more consideration than has been given to it in the past.

X. STATISTICAL SUMMARY SHOWING SCHOOL POPULATION AND EXPENDITURE

The reservations and qualifications which it is necessary to make in connexion with any educational statistics, particularly in Africa, may seem to invalidate all attempts to show comparisons by this means. The subject has been closely considered by the Colonial Office Advisory Committee on Education in the Colonies,

which has reached the conclusion that no figures so far available have great statistical value, owing to the diversity of methods employed in their compilation. As a result of their study, instructions have been issued by the Secretary of State prescribing a form in which the desired statistics shall in future be presented. The Commission on Higher Education in East Africa¹ likewise took the view that no comparative statistics could usefully be shown in its report. Notwithstanding these conclusions, an attempt is here made to summarize educational expenditure, and the percentages of native pupils in different schools, in tabular form, in the hope that these figures may be of interest and value. It cannot be too strongly emphasized, however, that the tables should be carefully studied in the light of the qualifications which follow, and that the figures should not be used without these important reservations.

The variety of statistical methods adopted in the different territories is so great as to make it difficult to institute any effective comparison, either in respect of the standard of education attained, or of the expenditure incurred. It is, for instance, difficult to secure any satisfactory basis for comparing percentages of native pupils in different school years owing to the variety of nomenclature adopted. In the Union the native schools follow the classification for European schools, the classes in the primary stage including two sub-standards and six standards. Elsewhere terms are found such as sub-grade, elementary, lower middle, upper middle, intermediate, central, and junior secondary; and enumeration of schools so classified would convey little unless numbers were given of the pupils studying in the different standards included in each school. The statistics in French and Belgian territories follow a different system and are not comparable with those of the British areas. Some attempt has therefore been made to make a classification of pupils in a few British territories according to standards, on the assumption that each standard corresponds with a year's work. Such a calculation is admittedly arbitrary and is offered subject to all necessary reserve. The figures for Nigeria are in particular doubtful, as classification figures are available only for the Southern Provinces.

¹ *Report*, op. cit., Colonial 142, 1937.

In regard to the number of pupils recorded, it must be noted that the figures for aided schools include a considerable number in respect of which no aid is given, for where state aid takes the form of block grants, it is not possible to say to which schools the block grant given to a mission is applied; it has, however, seemed preferable to include all the children who are recorded as in school, in order to obtain comparative figures of government expenditure. In Nigeria the children in Koran schools have been included, though they cannot be brought into comparison with pupils attending schools of a different type. It has also to be remembered that there are still many areas in which the smaller bush schools are concerned mainly with religious teaching.

Difficulties of comparison are no less serious in regard to expenditure. The very considerable educational expenditure of missionary bodies is not included, since it is not usually possible to isolate such expenditure from general missionary finance. The missions do not, as a rule, distinguish expenditure on education from that on other activities, and the growing tendency to make local missions as far as possible self-supporting leaves a large field of expenditure which is not brought into the accounts of home bodies. The proportion of expenditure met from mission funds, local receipts, and government grants respectively may be illustrated from the accounts of one of the missions working in Uganda. The home mission grant in 1935 was £17,987, the native contribution £13,333, school fees £17,667, and government grant £22,420. There is, moreover, a difficulty in connexion with fees. When the Education Department itself collects fees, these are credited to general revenue. Where fees pass through the missionary bodies, they do not appear as part of government educational finance.

Again, the expenditure figures shown in Table XI as government expenditure do not include the sums spent on education from native levies or native administrations. In Nigeria and Tanganyika native administrations are responsible for disbursing considerable sums, which are allocations from taxation revenue, on education. In the former territory, some thirty schools have recently been transferred from the central government to the native administrations. In Kenya the natives themselves have

taken the initiative in raising funds for education by means of special taxation imposed by the Local Native Councils. The bulk of the sums so raised has been expended in erecting schools which are administered by the government; assistance has also been given to mission schools and to private schools directly managed by natives. It should also be made clear that in South Africa expenditure on 'child welfare' has not been brought into account.

There is no uniformity of definition of educational expenditure. The figures given in column 2 are based upon the expenditure of the Education Departments. It should be noted that in some territories these figures include sums spent on vocational and technical education, while in others such education may be undertaken by the technical departments and will therefore not figure in the educational budgets.

Practice and circumstances differ also in regard to capital expenditure. One territory may build schools from loan funds, bearing an annual interest charge which would not, however, be debited to educational expenditure. Another territory may build schools out of revenue, and their cost may appear in the education vote. Similarly, in regard to maintenance, this is in most cases met from the Public Works Department vote, but there are exceptions even to this. It should be stated here that in the case of the South African education services expenditure in respect of loan charges on education buildings and in respect of pensions has been omitted, as these charges are not included under education expenditure in the colonies or mandated territories.

Finally, the division of education expenditure between Europeans, Asiatics, and Africans depends upon allocations of common expenditure, e.g. administration, inspectorate, equipment, which are in many cases arbitrary.

These are, in the main, the variations in financial administration which have to be borne in mind when the figures in Table XI are examined. In spite of this wide diversity of practice, the table does, it is suggested, give a fair indication of the funds expended by the different territories for the service which they regard as directly educational. It also gives an indication of the distribution of those funds among the pupils of different races in those territories where expenditure admits of racial analysis.

TABLE X
PERCENTAGES OF NATIVE PUPILS IN DIFFERENT SCHOOL YEARS

² Omits Northern Nigeria.

³ Omits unassisted Protectorate Schools. General Note. Unassisted schools omitted in South African provinces, and in Southern Rhodesia and partly in Sierra Leone.

CHAPTER XIX

THE EXTERNAL ASPECT OF AFRICAN ECONOMIC DEVELOPMENT¹

I. THE HISTORICAL BACKGROUND

THE first economic contacts of European countries with Africa, apart from the Mediterranean coast, sprang almost entirely from the slave trade and the trade with the East Indies. When Columbus and his successors first discovered the Americas, and when Bartholomew Diaz first rounded the Cape of Storms, Africa south of the northern tropic was virtually unknown.

Trade in African slaves had its origins as early as the days of Imperial Rome. It was continued through the period of the Moslem domination of North Africa, and African slaves were common in Arabia, Turkey, Persia, and even India, as well as along the northern coast of the continent. The trade received a new impulse with the sudden demand for labour in the Americas in the early years of the sixteenth century; Spanish, Flemish, and Genoese merchants were all concerned in the business, and after 1560 the English began to take their part. At first the slaves came principally from the rivers between Cape Verde and the Niger, but later, as the demand grew, the territories as far south as Angola were exploited. By the time that Vasco da Gama had consolidated the first achievements of Diaz by sailing round the Cape, up the East Coast to Moçambique and Melinde, and thence across the Indian Ocean to Calicut, the Portuguese had explored more or less thoroughly the West Coast, and had established a series of forts and stations from Cape Verde to the Congo. Once the way to India was known, these stations were quickly extended southwards and up the East Coast also. Here the Portuguese interest in African trade received an added stimulus from the search for gold.²

During the following three centuries control of the Indian route passed from the Portuguese to the Spanish, with the annexation of Portugal in 1580, to the Dutch in 1620, and, after the

¹ This chapter, and that which follows, were largely drafted by Mr. E. A. G. Robinson, Fellow of Sidney Sussex College, Cambridge.

² See Chap. XXII, pp. 1487 ff.

vicissitudes of the Napoleonic wars, with the decay of the Dutch East India Company, to the British in 1806.

During these three centuries colonization had been spasmodic and uneven, and limited in the main to small areas of cultivation in the immediate neighbourhood of the coastal forts. Only the Dutch settlements in South Africa penetrated inland; they extended by the end of the eighteenth century no more than one hundred and fifty miles from the southern coast, and were confined to the fertile territories below the escarpment of the Karoo. The relations of these Dutch colonists with the impecunious administration of the Dutch East India Company at the Cape had always been strained. Its supersession by the British increased the friction, and the arrival in 1820 of fourteen shiploads of British immigrants added to the existing difficulties and complaints. Finally, after the emancipation of the slaves, the first great trek northward took place in 1836, when ten thousand *voor-trekkers* attempted to remove themselves from the vexations of British rule.¹

The penetration of other parts of Africa took a more leisurely course. During the last three and a half centuries parts of the interior had been explored and mapped by some few scores of explorers of all nations. But a school atlas of 1850 would show an interior to the continent scarcely as well surveyed as is the Antarctic to-day. Gradually the journeys of such travellers as Mungo Park, Richard Burton, José de Lacerda, Heinrich Barth, David Livingstone, Henry Stanley, and many others of lesser fame, and of the missionaries (who, from the time of the Jesuits who first accompanied the Portuguese, penetrated farther and stayed longer than all save the most adventurous of the explorers), filled in these gaps and made the resources of the country known.

The knowledge thus gained spurred Leopold of Belgium to carve out for himself what was virtually a vast private estate on the upper Congo. The probability of a similar extension of European influence north of the Zambesi brought the Powers together in the Berlin Conference of 1884-5, where it was sought to bring order into the scramble for territory. It was agreed that claims for territory must be notified to the other signatory powers and that they must be supported by evidence of occupation. But since

¹ See Chap. V, p. 130.

occupation, in the sense of the presence of settlers, traders, mission stations, government offices, might not be immediately effective, 'spheres of influence' were to be recognized. Thus, outside the limits of the four republics in the south, Africa remained until the last years of the nineteenth century essentially a 'continent of outposts'.

So soon as the division of territories was completed, some attempt not only at political but also at economic penetration and development was begun. But in the initial stages progress was slow and the difficulties encountered were many. Distances were great and the supply of labour scanty. The richest natural resources may have little economic value if they are many hundreds of miles distant from ports and places of consumption, and if plentiful labour is not available for their exploitation, and the resources of Africa, great as they undoubtedly are, have suffered from both of these handicaps.

In such conditions it was not easy to secure from outside sources the capital that was necessary for economic development, or to create a surplus of exports out of which interest payments on that capital could be met. This difficulty was overcome in South Africa by the discovery of diamonds in 1866, which provided a valuable export unaffected by the high cost of transport and requiring little capital for its immediate exploitation.¹ The foreign capital employed in the industry has probably never exceeded £20,000,000; the majority came from the profits of the industry itself. Already by 1882 the annual value of diamond exports had reached approximately £4,000,000, twice the amount of all other exports before the discovery of diamonds.

The immediate effects were significant. South Africa had hitherto depended primarily on the proceeds of an extensive and casual agriculture. The community was poor and not very numerous. In 1865 the total European population of the Cape Colony did not exceed 181,000. The taxable resources for internal development were slight, and in bad years virtually disappeared. Moreover, foreign capital, even if it could be attracted, could do little to remedy the difficulties of the colonists. Low-rated agricultural exports and the few imports that such a community could afford would serve scarcely to cover the operation and depreciation costs of rail-

¹ See Chap. XXII, pp. 1509 ff.

ways, quite apart from the heavy interest charges. Indeed, when the diamond discoveries were made, no more than fifty-eight miles of railway existed in Cape colony. The first extensions, made possible by mineral discoveries, joined Kimberley with the Cape and with Port Elizabeth and East London.¹ Moreover, when gold began to be mined on the Rand in 1886, the capital for its exploitation could be readily obtained, both from those who had made profits in diamonds and from foreign investors who were already familiar with Africa as a place of investment and with the personalities of the leading figures in the diamond world, now associated also in the gold-mining enterprises. The capital for railway extensions could be borrowed on reasonably easy terms. Finally, the diamond diggings served to demonstrate the field in which African labour could collaborate with European technique and European capital to the greatest profit. In an extensive system of agriculture cheap native labour is of relatively small advantage, and did not in Africa suffice to overcome the handicap of distance, high transport costs, and lack of facilities. In mining, the close supervision of more routine tasks has increased the relative efficiency of native labour, and transport costs have proved less of an impediment.

In the territories economically less fortunate than the Cape, development was slower and more difficult, and in many cases took the form of exploitation by powerful companies, furnished usually with some measure of monopoly power, and armed often with responsibilities also for political administration. Their dual position enabled them, however, to take a wider view than could either a private merchant or a government debarred from trading activities, of what might be regarded as profitable expenditure upon long-range developments. They could set their gain from the expansion of native or general trade against increased costs of administration, or in later days the appreciation of land values or the profits of mineral exploitations, against the probable losses of railway operations.

Companies of merchant adventurers to the West Coast of Africa had received charters from Queen Elizabeth. The Royal African Company had enjoyed a charter from Charles II, granting it a monopoly of the trade of the whole coast from Morocco to the Cape

¹ See Chap. XXIII, p. 1565.

Colony. These earlier monopolies had in most cases been suppressed, or had fallen into abeyance, during the anti-monopolist agitations at the close of the seventeenth century, though powerful associations of merchants in several instances continued to draw subsidies and to administer the forts and trading stations. The principle of development through the agency of companies was, however, widely revived during the years preceding and following the Berlin Convention. In British territories the Royal Niger Company, the Imperial East Africa Company, the Chartered Company of Nyasaland, and Rhodes' British South Africa Chartered Company all served to expand British trade and influence, despite the apathy, which in the earlier years at least grew sometimes into antagonism, of the government at home. In the Belgian territories the *Compagnie du Congo pour le Commerce et l'Industrie* was founded in 1886, and established a series of subsidiaries for the development of particular areas or activities. In French Equatorial Africa an epoch of concessions to companies was inaugurated in 1899. In the Portuguese possessions the Moçambique Company and the Company of Mossamédès, amongst others, possessed almost unlimited powers over a wide area. In the German territories the *Deutsche Ostafrikanische Gesellschaft* and the privileged companies in South-West Africa and in the North and South Cameroons were established upon similar lines.

The companies differed much in size, in the responsibilities imposed upon them, and in the efficiency with which they carried out their varied tasks. Many of them at the end of a comparatively short period found themselves obliged either to cease operations entirely or considerably to curtail their activities. An exaggerated belief in the natural riches of the territories, and an entire misconception of the difficulties of their exploitation, had led in some cases, though not in all, to the loss of vast sums in misguided attempts to reap quickly without sowing.¹

In the territories unsuited to European settlement the earliest attempts to develop trade sometimes involved the destructive spoliation of the resources of the colony. Rubber or forest timber was exhausted without proper replacement; accumulations of ivory were for a period obtained by exchange for cheap imports.

¹ See, for example, Chap. XII, p. 787.

But such a policy of exploitation could not continue indefinitely. Once the realities of the situation were understood, capital was less easily attracted. But the creation of expensive public works, in particular of harbour works and of railway facilities, was more clearly seen to be an essential condition to the effective *mise-en-valeur* of the various territories. The Niger and the Congo and their tributaries have always provided important roads into the interior, but both required to be supplemented by railways, and the Congo to be connected from a point above the rapids to suitable points below.¹

As knowledge extended it became increasingly apparent that African territories could be developed only if capital construction were undertaken of a type which seemed likely to yield a return too uncertain and too distant to justify investment even by a chartered company. Moreover, experience increasingly showed the difficulties of reconciling the responsibilities of administration with the interests of shareholders, and of demarcating justifiable administrative compulsion from forced labour for the purpose of profit-making. In consequence the first decade of the twentieth century saw in many territories an attempt to recover the earlier grants of concessions and to separate more distinctly the functions of trading and of government. French, Belgian, and German policy early moved in this direction. In British territories, from 1900, when Nigeria became a protectorate, the administration has in one case after another been transferred to the Crown.

In recent years, however, as will be shown in the next chapter, there has been some partial return to the earlier policy with regard to concessions. As governments have become more strongly established and more widely spread, they have been less liable to domination by powerful concessionaires, and the merits as well as the defects of such companies have come to be recognized. The large company can often afford an organization to control the conditions and welfare of its native employees that would be beyond the reach of the best-intentioned small employer.² Its operations can be more easily controlled than those of a multitude of small undertakings. Belgian observers are not slow to point to the marked difference of conditions at the Lupa and Kilo-Moto gold fields,

See Chap. XXIII, pp. 1591 ff.

² See Chap. XI, pp. 672 ff.

both engaged in working alluvial, but the latter under the management of a well-organized company in which the state retains an interest.¹ The company enterprise, again, can often afford to take a longer view of the advantages of training and educating workers and of developing new types of industry or new forms of agricultural produce.

As economic development proceeded, wide differences began to appear between the various territories. Where, as in the Union and Southern Rhodesia, a territory enjoyed both the advantages of a climate suited to white settlement and minerals ready to be worked, development came quickly. Where, as in Kenya, settlement was possible, but minerals were at first scarce or unprofitable, development was slower and more precarious. Where, again, as in Nigeria and the Gold Coast, the possibility of cultivating export crops existed, but white settlement was impossible, economic development took a substantially different form. Where, finally, as in French Equatorial Africa, in parts of the Belgian and Portuguese colonies, and of Northern Rhodesia and Tanganyika, none of these advantages existed, an economic backwater remained, and native life followed its traditional forms, with little change save that consequent upon the imposition of peace.

During the first two decades of the twentieth century the problem of the end and of the methods of colonial economic administrations came by degrees to be more clearly formulated, and conservation and development gradually became the chief characteristics of economic activity.

II. THE DEVELOPMENT OF AFRICA BY FOREIGN CAPITAL

So far as concerns the actual stages of economic penetration, railway building took the first place, apart from early attempts at the exploitation of minerals. As a consequence of the widespread transfer of responsibilities from the earlier companies to administrations directly under the control of the imperial powers, the task of railway construction and operation passed increasingly into the hands of the various governments. The latter could sometimes secure an economy through departmental construction. More frequently the political urgency of speedy completion was the

¹ See Chap. XI, p. 650, and Chap. XXII, p. 1507.

primary argument for that course. But, since the main reason for government operation was the lack of a sufficient prospective profit to attract the private investor, the inter-relations of railway and government finances have in many colonies been complicated. It has rarely been possible, save where a profitable mineral traffic has been available, for railways to earn a normal return on their capital. The profits of the South African Railways have been secured largely from the service of the gold-mining community of the Rand. The Rhodesia-Katanga copper mines, with four outlets to the sea, at Beira and Dar-es-Salaam to the east, and at Matadi and Lobito Bay to the west, have brought from time to time relative prosperity to whichever route was fortunate enough to carry a large volume of the output.

It is clear that the development of less accessible areas, whether from the point of view of the raising of native standards of life, or from that of European colonization, or again from that of the creation of raw material supplies, can only be solved if cheap transport facilities are first provided; but further railway construction¹ is not likely to be undertaken on any large scale, unless a distinction can be drawn between strictly commercial operations and extensions which are for development purposes, and which, however wise in the light of long-run considerations, cannot be expected to bring an early return to the private investor.

The important part that railway construction has played in the opening up of African trade can best be indicated by its share in the total investment of capital in African enterprises south of the Sahara. In the course of a study which is being published as an accompaniment to this Survey, Professor Frankel has made an estimate of the total of foreign capital that has been employed in the development of such African undertakings down to the close of 1934.² According to his calculations, out of a total investment of about £1,222,000,000 no less than £384,000,000 was required for investment in railways. Of the total loans raised by the governments of British territories in Africa, as much as 75 per cent. was for railway purposes. The following table shows the distribution of this investment according to territories.

¹ See Chap. XXIII, p. 1608.

Professor Frankel, in estimating the total investment of foreign capital in African territories, has based his calculations mainly upon the figures of new capital issues published from time to time by the *Economist*.³ These figures exclude non-listed capital, invested directly by immigrants in agriculture or in small mining or commercial enterprises, and also such foreign capital as is employed in Africa by firms whose main operations are elsewhere, and whose capital is not therefore classified as raised for African purposes. For this non-listed capital a somewhat arbitrary provision has had to be made.

He has estimated that a total of about £1,222,000,000 had been invested from abroad up to the end of 1936. Of this, about £546,000,000 took the form of loans and grants to governments;

¹ Ibid.

² The Beira and Beira Junction Railways, and the Trans-Zambesi Railways, having been built mainly with British capital, have been included with the Rhodesia and Nyasaland railways respectively, of which they in effect form extensions to the sea-coast.

³ Professor Frankel's figures, following the practice of the *Economist*, are designed to show only the cash subscription and not the nominal capital. Where an issue has been for the purpose of buying out an existing undertaking he has eliminated vendors' shares where they led to little or no inflow of capital from abroad, but where they have been largely sold to foreign holders they have been included. So far as possible double counting through the inclusion of banking, finance, and holding or insurance companies as well as their subsidiary operating companies, has been eliminated.

about £581,000,000 took the form of 'private listed capital', the public issues, that is, of companies; about £95,000,000 was the estimated total of non-listed capital. This last figure has been obtained merely by estimating for each territory the ratio (varying from 5 per cent. to 15 per cent.) of non-listed to listed capital. There is a considerable margin of probable error in these estimates, but since the figure of non-listed capital is small relatively to the total the added margin of error in the final figure is not great.

Of the total of £1,222,000,000, about £523,000,000 is the estimated share of the Union of South Africa, which is 42·81 per cent. of the investment in all territories, and 55·54 per cent. of that in British territories. Of other British territories, the most important fields of investment have been: the Rhodesias, which have taken about £102,000,000, Nigeria, £75,000,000, Tanganyika, £52,000,000, Kenya and Uganda, £46,000,000, the Sudan, £43,000,000, the Gold Coast, £35,000,000, and South-West Africa, £32,000,000. The total investment in all British territories is estimated to have been some £941,000,000 to the end of 1936, which is about 77 per cent. of the whole.

In non-British territories the greatest investment has been in the Belgian Congo, where it is estimated to have been £143,000,000. In the French territories the estimated total is £70,000,000, of which about £30,000,000 is in French West Africa, and £21,000,000 in French Equatorial Africa. The estimated investment in the Portuguese territories is about £67,000,000, divided fairly equally between Angola and Moçambique. Thus in the Belgian territories there is about 11·73 per cent., in the French 5·76 per cent., and in the Portuguese 5·46 per cent. of all the capital invested.

The meaning of these figures, so far as they concern economic development, can most clearly be seen by calculating the investment per head of population. It must be remembered that they represent only the foreign investment, and in the more highly developed territories there is a very considerable added local investment, both of private capital and of public money, spent upon capital improvements. The total capital that has brought Africa to its present stage of development, or the capital that would be needed to raise a territory from its present to a higher stage of development, is thus very substantially greater than is indicated

by these figures of capital imported. The foreign investment in the Union amounts to about £55·8 per head of total population, European, Asiatic, coloured, and native. It is about £38·4 per head in the Rhodesias, about £8·1 per head in British East Africa, and about £4·8 in British West Africa. In Nigeria it is only £3·9 per head. It is about £13·0 in the Belgian Congo. In Angola and Moçambique it is about £9·8 per head, though the railway and port developments of both these territories serve much more than the local populations. It is lowest in the French colonies, about £3·3. In French West Africa it is no more than £2·1 per head.

Three main facts emerge from Professor Frankel's analysis. First, the Union, with its more highly developed modern economy, has absorbed a very large part of all the capital that has gone to Africa. Second, it is the highly mineralized territories which have received the greater part of the capital; in the others the capital per head remains in most cases comparatively small. Third, investment controlled by governments has been a very important part of the whole, about 44·72 per cent. for all these territories together, and about 47·68 per cent. for the British territories. The proportion tends to be lowest in the more highly mineralized territories, where there has been extensive borrowing for mining undertakings, and highest in those territories where railway construction controlled by the government has been almost the only important form of economic development. In the Union 'public listed capital' was, according to Professor Frankel's estimate, 42·85 per cent. of the whole. In the Rhodesias, where during the British South Africa Company's rule private enterprise was naturally an important part of the whole, it was 38·68 per cent. of all capital. In the Gold Coast it was 38·13 per cent., and in Nigeria 46·24 per cent., mainly as a consequence of the large quantities of capital employed by the big trading companies. On the other hand, in Nyasaland it was 84·79 per cent., in the Sudan 83·37 per cent., in Sierra Leone 72·95 per cent., in Kenya and Uganda 68·36 per cent., and in Tanganyika 60·14 per cent. In the French territories the proportion is in general close to the latter group. It was 71·72 per cent. in Equatorial Africa, 60·71 per cent. in Togo and the Cameroons, and 54·15 per cent. in French West Africa. In the Portuguese colonies, where British private capital had provided a large part of the

whole, it was no more than 27.92 per cent. In the Belgian Congo and Ruanda-Urundi the very great investment in mining, and the construction of railways by private capital, have reduced the share of 'public listed capital' to 25.01 per cent. of the whole. As has been remarked elsewhere¹ the state has a large financial interest in many of the more important industrial and commercial undertakings, but this is not fully explained by the figures of 'public listed capital'. The nature of the holding is best illustrated by the details given in Chapter XXII regarding the constitution of the *Union Minière* and Kilo-Moto companies.²

The 'public listed capital' takes in the British colonial territories three forms: loans, grants-in-aid, and grants from the Colonial Development Fund. It has also to be remembered that in the West African colonies, and to some extent elsewhere, the military garrison was for a considerable time paid directly from England and the cost did not appear in colonial accounts. Of a total of £449,000,000 for the Union and British colonies, some £394,000,000 are loans, of which £224,000,000 are to the Union,³ and £36,000,000 to Southern Rhodesia. In addition there have been grants-in-aid, amounting in all to £52,000,000. This figure includes, however, the German grants made before the War to Tanganyika and South-West Africa. If these are excluded, the total of grants to British territories is no more than £27,000,000. The bulk of these grants was, of course, made in the early years before the territories could be brought into a position where revenue balanced expenditure. Of the remaining territories, the Anglo-Egyptian Sudan has received the most, £10,800,000. Nigeria (including an appropriation for the compensation of the Niger Company) has received £5,700,000. No other territory has received over £3,000,000. Since 1929 grants for new colonial developments have been made from the Colonial Development Fund.⁴ Its grants to African territories amounted by

¹ See Chap. XI, p. 645.

² See pp. 1506-8.

³ See S. H. Frankel, *op. cit.*, Table 28, p. 158.

⁴ Under the Colonial Development Act, 1929, an annual sum not exceeding £1,000,000, and in practice varying usually between £400,000 and £900,000 according to the demands upon the fund, is voted by parliament. Free grants or loans may be made from the fund to colonies not possessing responsible government, protectorates and mandates, for the purpose of aiding and developing agriculture and industry in their territories, and promoting commerce with and industry in the United Kingdom.

the end of 1936 to approximately £3,000,000. Of this, about a half has gone to East Africa, including important grants to Nyasaland for railway and bridge works. Thus the total of the British grants from public funds is no more than some £30,000,000.

It is greatly to the credit of British administration that it so quickly brought these African territories to a position of financial independence. But it has sometimes meant that developments which could provide no attraction to private enterprise, and could not sustain the relatively high interest rates at which these governments have been obliged to borrow, have necessarily been long postponed or seriously curtailed. If at any time the existence of an unemployment problem requires the examination of methods of providing work in Great Britain, the possibility of further grants to assist African governments to purchase railway, bridging, or other capital equipment might perhaps be considered with advantage to both parties.

Of the 'public listed capital' in British territories over half has been invested in railways. The total investment in these is, as was shown above, about £271,000,000. Of the 'private listed capital' a large share has gone to mining. In the Union the diamond mines have probably taken some £20,000,000 of foreign capital. The gold mines have provided a much larger source of demand. Up to 1932 they had absorbed about £148,000,000 of invested capital, and about £63,000,000 of reinvested profits.¹ Of this investment, about £120,000,000 came initially from abroad. Since 1932 there has probably been about £24,000,000 of further foreign investment in gold mines. Thus of the £251,000,000 of 'private listed capital' in the Union, roughly two-thirds has gone to finance

The particular means specified in the Act include: encouragement to the adoption of improved machinery and equipment for cultivation or the preparation of agricultural produce for the market; the improvement of internal transport; the construction and improvement of harbours; the development and improvement of fisheries; forestry; surveys; the reclamation, drainage, and irrigation of land; improvement of water supplies and water power; electricity supply; promoting the development of minerals; scientific research and experiment likely to assist agriculture or industry; public health; assistance for not more than ten years in meeting the interest charges upon loans raised for certain purposes. The fund is administered by a committee of seven members. The total assistance approved to British colonies in all parts of the world was £7,284,682 at March 31, 1938, of which £3,025,168 was loans and £4,259,514 grants. Of this about 55 per cent. had gone to African territories.

¹ S. H. Frankel, *op. cit.*, chap. v, p. 89.

mining enterprises. In the Rhodesias probably about £47,000,000 has been used for this purpose. There were, it is true, large issues of nominal capital in Southern Rhodesia in the early years of its development—the figure was about £44,500,000 before 1904. But of this barely a quarter had been subscribed in cash. The great copper developments of the last decade have brought nearly £25,000,000 of foreign capital to Northern Rhodesia.

Of the other British territories, only Nigeria, the Gold Coast, Sierra Leone, Kenya, Tanganyika, and South-West Africa have important mining interests. In none of these has the investment been on a scale comparable with that of the Union and the Rhodesias. In Kenya, Tanganyika, and South-West Africa much of the development has been undertaken by individual prospectors with little financial backing from abroad. Of the £43,000,000 of nominal capital concerned in the 1904 gold-mining boom in the Gold Coast, only a small fraction found its way to the territory in the form of actual investment. The total mining investment in all these territories is probably in the neighbourhood of £15,000,000 to £20,000,000.

Of the non-British territories, the Belgian Congo has been very much the most important field of mining investment. The capital invested for this purpose was probably already about £13,000,000 at the outbreak of the War.¹ Since then there has been a further investment, made at various times, and at various stages in the depreciation of the franc, which may be valued very approximately at another £17,000,000, making about £30,000,000 in all.

Thus in round figures the mining investment in Africa south of the Sahara may be put at £260,000,000, of which just about two-thirds is that of the Union. This represents a little more than one-fifth of the total investment, and more than two-fifths of the 'private listed capital' invested.

This investment, important as it has been in bringing Africa to her present stage of economic growth, is yet small in comparison with the vast amounts of capital which have through the centuries been invested in the development of the older countries and more particularly of the European countries. The present value of the capital investments in Great Britain may be very roughly put at

¹ S. H. Frankel, *op. cit.*, chap. v, p. 167.

£14,000,000,000, and that figure, though it includes an estimate of the value of roads and other social capital, nevertheless scarcely reflects the vast sums which have been sunk in many forms of public and private improvements and continue even after a long lapse of time to increase the amenities of life.

No reliable figures exist which will show the return on the total capital invested in Africa. The diamond mines have paid dividends between 1886 and 1934 exceeding £80,000,000 on an investment of some £20,000,000.¹ The Rand gold mines, according to a calculation of Professor Frankel, have not given any correspondingly high rate of return. For the years 1886-1932 they yielded an average of approximately 4.1 per cent. upon the capital invested. But the sheer magnitude of the investment has secured that a large total of dividends has been distributed to foreign investors.² The earnings of the chartered companies, on the other hand, have never been spectacular, and when the investments which were wholly or partially lost are taken into account the average of earnings has almost certainly been lower than would again induce the investors to embark their capital.

As regards the rate of interest on government loans, for a fully satisfactory analysis both the terms of the original issue and of the ultimate repayment would need to be taken into account. Such an analysis would require the detailed examination of a host of individual issues, which is for the moment impossible. The nominal rates of interest have, however, been analysed for the British territories by Professor Frankel.³ In 1913 the average rate in British Africa as a whole was 3.44 per cent. The large external debt of the Union was paying an average charge of 3.39 per cent., and 49.6 per cent. of the debt was at a rate of 3 per cent. For the remaining British territories the average rate was just 3½ per cent., and 83.3 per cent. of the whole was actually paying that rate. By 1932 the average rate for all territories had risen to 4.37 per cent., that of the Union's external debt to 3.97 per cent., and that of others to 4.85 per cent. By 1935 the average rate had declined to 4.18 per cent., that for the Union's external debt to 4.01 per cent., and that

¹ See Chap. XXII, p. 1512, and S. H. Frankel, *op. cit.*, p. 53.

² S. H. Frankel, *op. cit.*, chap. iii, pp. 88-9 and 91.

³ S. H. Frankel, *op. cit.*, Table 34, p. 174.

of others to 4.72 per cent. In 1935, of the Union's external debt of about £123,000,000, there was 47.7 per cent. at 3½ per cent. or lower rates, and 33.7 per cent. at as high a rate as 5 per cent. Of the remaining territories' loans, amounting to over £99,000,000, there was 48.5 per cent. at 5 per cent. or higher rates, including 18.7 per cent. of the whole at 6 per cent; only 14 per cent. of the government loans were bearing interest at rates below 4 per cent.

The Union's external debt, which was £108,000,000 in 1913, had increased to £166,000,000 in 1932. By 1935 it had diminished to £123,000,000, being replaced by internal debt. This had been no more than £11,000,000 in 1913; it was £125,000,000 in 1935. Thus the internally-held debt now exceeds the foreign debt. The other territories were indebted for no more than £12,500,000 in 1913. By 1935 their debt had risen to £99,000,000. Of this increase the greater part had taken place before 1925. By that year their combined debt had risen to £64,000,000. The high rates at present paid are thus in large measure a consequence of attempted expansion in the years of high interest rates immediately following the War, and those rates will continue, in the absence of special opportunities for conversion, for some years to come, since the same factors which required a high level of interest were held to require a long-term loan at that interest. Thus the Nigerian 6 per cent. loan of 1919 is redeemable between 1949 and 1979. The Gold Coast 6 per cent. loan of the same year is redeemable from 1945 to 1970, and the similar loan of Kenya of 1921 at any time after 1946. The debts at 5 per cent., mostly incurred in the early 1920's, are largely repayable during the late 1940's or early 1950's. In view of the fact that these loans were guaranteed by the British Government some surprise may be felt that it was necessary to issue them at so high a rate, and that more use could not be made of the system of short-term bonds. By 1931 a number of territories were able to borrow at 4 per cent., and between 1932 and 1935 there has been nearly £5,000,000 of loans at 3 per cent.

III. AFRICA'S SHARE IN WORLD TRADE

Africa's share in world production remains, despite this great investment, comparatively small.¹ The share of the whole con-

¹ The figures quoted in the remaining sections of this chapter and in the succeeding

tinient (and not merely of that part which lies south of the Sahara) was in 1929, according to calculations made by the Economic and Financial Section of the League of Nations, approximately 4.5 per cent. of the world's export trade and 4.8 per cent. of the world's import trade. The shares of Africa south of the Sahara were no more than 2.8 and 2.6 per cent. respectively. These latter figures are almost identical with those for Oceania, and may be contrasted with the figures of 19.5 and 16.0 per cent. for North America, and 48.8 and 55.8 per cent. for Europe. If alternatively Africa's share in economic activity is measured in terms of the production of primary commodities, the results are not very different. The figures of world production analysed by the Economic Intelligence Service of the League of Nations are not, unfortunately, in such form as to make it easily possible to distinguish what proportion of world output comes from Africa south of the Sahara. If the figures for Africa as a whole are used, the share of the world primary production coming from the African continent was estimated to be 2.4 per cent. for the years 1925-9, the share of the whole continent in this case being almost equal to that of Oceania, and in marked contrast to the 43.3 per cent. of Europe, including the U.S.S.R., and to the 30.4 per cent. of North America. Since 1930 the African share has been increasing (in 1935 it was 2.8 per cent.), but this was in a large measure a consequence of the relative decline in North American production, resulting from the exceptional severity of the depression there, and was only in part to be explained by actual increases of African production. In agricultural products generally the share of Africa was somewhat greater, being 2.8 per cent. for 1925-9; in non-agricultural products it was substantially less, being 1.0 per cent. of the whole for those years. Between 1925-9 and 1935 there was an increase, to 3.2 per cent. in the former and 1.3 per cent. in the latter case.

But if we turn to individual commodities the share of Africa is in many cases very much greater than this. While Africa's share in the world production of metals generally was no more than

chapter are in the main derived from unpublished tables and memoranda prepared for this Survey by Dr. Charlotte Leubuscher, formerly Professor of Economics in the University of Berlin, and now Research Fellow of Lady Margaret Hall, Oxford. Upon her preliminary studies these chapters have been largely based. For her published work, see footnote on p. 689.

1.2 per cent. for 1925-9, and 2.5 per cent. for 1934, her share of gold production was 56.0 per cent. in the former years, of chrome ore 50.6 per cent., of manganese ore 16.4 per cent., of platinum 12.0 per cent., of tin ore 6.3 per cent., and of copper 7.3 per cent. It is impossible to state exactly her share in the world's output of radium and of vanadium. In each case it is almost certainly true to say that more than half of the world's output comes from Africa. Of non-metallic minerals generally the African share was estimated to be 2.3 per cent., but Africa contributed some 14.8 per cent. of the world's output of asbestos, and 11.9 per cent. of the world's output of graphite. The years of depression brought significant changes in the proportion that the African output of these metals bore to world production. In chrome ore the African share (mainly from Southern Rhodesia) fell to 17 per cent. in 1933, while in the case of copper it rose to 21.5 per cent., and in the case of tin to 8.6 per cent.

In raw materials generally the African share of production was for the years 1925-9 estimated to be 2.6 per cent. of the world production, rising to 3.1 per cent., again largely in consequence of the great decline of North American production, in 1935. But for the years 1925-9 Africa produced 93.6 per cent. of the world's palm and palm-kernel oil, 62.9 per cent. of the world's cocoa, 23.7 per cent. of the world's groundnuts, 7.7 per cent. of the world's sesame, 9.8 per cent. of the world's wool. The share of Africa in the world's sisal output is somewhat uncertain, as output figures for some of the chief producing areas do not exist. It is believed that Kenya and Tanganyika produce about one-third of the world's supply. Of some other products, the output, though large and important to the economy of some of the African territories, forms only a very small part of the world's total. Thus in 1932 African coffee was only some 2.5 per cent. and African tobacco 1.3 per cent. of the whole.

As in the case of metals, there have been considerable changes in the African share of the output of some of these products in recent years. The proportion of African production of palm and palm-kernel oil fell to 77.8 per cent. in 1933. That of cocoa had risen to 68.5 per cent. That of rubber, which was 0.7 per cent. of world output for the years 1925-9, had fallen by 1933 to the low

level of 0.2 per cent. On the other hand, the African share of ginned cotton had risen from 7.3 per cent. for the earlier period to 8.7 per cent. in 1933, and that of cotton seed is almost the same proportion.

It will be seen from the figures given above that Africa's share in international trade is considerably greater than her share in primary production. In 1929 her share of trade was 4.6 per cent., and her share in world primary production 2.5 per cent.; thus, in the case of Africa, production for export is relatively more important than in the world as a whole. This is in part an ordinary phenomenon of any country in the stage of economic development preceding the growth of local industries; it is in part a consequence of the relation between colonies and mother countries which peculiarly affects the continent of Africa. The abrupt transition from a primitive self-sufficient economy to a system of economic inter-dependence with the rest of the world, and more particularly with those countries which had provided the capital for the opening up of Africa, and now required to be paid interest on their investments, made necessary the rapid expansion of export crops. This need was reinforced by the problem confronting the native of discovering a means to earn money to buy imports and to pay his taxes. The solution has differed widely in different parts of Africa, but within single territories one crop or one product in many cases provides an unusually large proportion of the whole export. The Gambia, depending to the extent of 98 per cent. upon its export of groundnuts, is an extreme instance. Zanzibar derived 73 per cent. of its export income in 1935 from cloves, the Union of South Africa and Southern Rhodesia 72 per cent. and 64 per cent. respectively of theirs from gold, Northern Rhodesia 61 per cent. from copper, Uganda some 80 per cent. from cotton, Nigeria and Sierra Leone 35 per cent. and 47 per cent. respectively from export of palm oil and palm kernels. In some other territories the extent of dependence upon a single product has been somewhat lessened in recent years, but still remains considerable. Thus Nyasaland as late as 1932 was dependent to the extent of 86 per cent. of her exports upon tobacco, but by 1935 the growing output of tea and cotton had reduced this proportion to 42 per cent. In the case of the Gold Coast, in 1929 cocoa accounted for 79 per cent. of all exports, but by 1935 expansion of gold output

had reduced this to 56 per cent. In non-British territories the dependence upon single products or crops has been somewhat less, though groundnuts formed 49 per cent. of the exports in 1934 of French West Africa, cocoa 31 and 30 per cent. of the exports of the French Cameroons and of French Togoland, and sugar 66 per cent. of the exports of the area administered by the Moçambique Company and 26 per cent. of those of the area administered by the government in Portuguese East Africa.

This high degree of dependence upon the fortunes of a single commodity, and not infrequently also of a single market, has rendered many of those African territories very susceptible to the risks of industrial fluctuations. While the chief gold-producing territories have been relatively immune from this danger, indeed in a sense hedged against it, those which are mainly concerned in raw material production have suffered severely. Thus, Sierra Leone and Nigeria have suffered falls of 53 and 52 per cent. respectively in the value of their exports between 1929 and the worst of the subsequent five years, Kenya and Uganda a decline of 39 per cent., and Tanganyika and the Gold Coast, despite a growing output and value of gold production, declines of 56 and 39 per cent. respectively. But these reductions, grave as have been their effects upon the financial position of the territories involved, are not unparalleled in other continents. In the period under consideration (1929-34) the total recorded value of world exports, measured in gold dollars, declined by no less than 66 per cent. Africa, with a total decline of 48 per cent., suffered less than any other continent, and markedly less than North America, where the total decline was no less than 73 per cent. The effect of a sudden fall in prices differs widely in countries of a highly organized economy and in those where the organization is of a simple character. In Africa the period of depression had an early and significant effect on government finances,¹ and was also widely felt by wage-earners, with the exception of those employed in the gold mines or their connected industries. But it was felt in a minor degree by the large part of the population which is either occupied in cultivating subsistence crops or is able to turn to them when commercial crops cease to be remunerative.

¹ For detailed figures, see S. H. Frankel, *op. cit.*, Table 38, p. 184.

IV. THE DESTINATIONS OF AFRICAN EXPORTS

To distinguish the exports of African territories according to their countries of destination with any satisfactory accuracy is unfortunately impossible. The statistics prepared by a number of governments give information only of the country of immediate consignment, and where statistics indicate the country of destination it is far from clear where the ultimate consumption will take place. The shipping facilities available may dictate the immediate destinations of exports, and the existence of an entrepôt trade, or of refineries, or facilities for some primary process of manufacture, may result in far greater consignments to particular countries than are accounted for by final consumption. Thus in 1934 the Belgian Congo is shown as having exported in all 131,769 metric tons of copper. Of this, 40,201 tons appear as consigned to Belgium, 42,144 tons to Moçambique, 24,181 tons to Angola, and only 16,051 tons to Germany. On the other hand, the German customs figures for the same year show an import of 24,876 tons from the Belgian Congo, and a further 12,211 tons from the Belgium-Luxemburg customs-union, most of which probably came originally from the Belgian Congo. Such instances can be multiplied indefinitely, and go far to invalidate any general inferences which might be made upon the basis of published statistics. But if these difficulties are borne in mind, some analysis of the destinations of African exports may nevertheless be undertaken.

If we take first the British territories, from the Union of South Africa, South-West Africa, and the South African protectorates some 75 per cent. of the domestic exports, including bullion, was sent in 1934 to the United Kingdom, but this high percentage is very largely accounted for by the consignment of gold to London, and, if bullion be excluded, slightly less than 40 per cent. of all domestic exports was to the United Kingdom, some 16 per cent. to the rest of the British Empire (including, of course, other African territories), and nearly 44 per cent. to foreign countries. From the remaining British territories in the same year the proportion of exports sent to the United Kingdom was slightly less than 39 per cent., to the rest of the Empire about 16 per cent., and to foreign countries approximately 45 per cent. The change in these propor-

tions during recent years has not been considerable. The main difference since 1929 has been a decline of 3·4 per cent. in the share of foreign countries, mainly accounted for by the increased proportion of trade within the Empire, including trade between British African dependencies, which has risen from under 12 per cent. to approximately 16 per cent. of the whole.

These general figures conceal comparatively wide differences between individual territories, and between individual products. There is a small number of territories whose export trade is almost exclusively with the United Kingdom. These include Nyasaland, sending 96·8 per cent. in 1934, the Gambia 88·6 per cent., and the British mandated territory in the Cameroons, 93·8 per cent. Southern Rhodesia, if bullion is included, sent 72·9 per cent.; but if it is excluded, the United Kingdom's share of exports was no more than 40·6 per cent. An intermediate group sends rather more than half of its exports to the United Kingdom. This group includes Sierra Leone, 62·3 per cent. in 1934, and Anglo-Egyptian Sudan, 52·7 per cent. Finally a large number of territories have a greater trade with foreign countries, and with the rest of the British Empire, than with the United Kingdom itself. Thus Nigeria in 1934 exported 45·9 per cent. of its goods to the United Kingdom and 52·3 per cent. to foreign countries, of which 12·3 per cent. went to Germany, 12·1 per cent. to France, and 9·9 per cent. to the United States. The Gold Coast sent only 37·3 per cent. of its exports, apart from bullion, to the United Kingdom, and 60·0 per cent. to foreign countries, of which 22·2 per cent. went to the United States and 19·7 per cent. to Germany. Northern Rhodesia sent 44·2 per cent. to the United Kingdom and 53·8 per cent. to foreign countries, of which Germany took 24·4 per cent., entirely in purchases of copper and zinc.

In the two mandated territories of Tanganyika and South-West Africa the direct trade with the United Kingdom is not predominantly large. In the case of Tanganyika the exports to the United Kingdom are shown to be 27·4 per cent. of the whole, including gold, and 18·3 per cent. excluding gold. But some correction requires to be made to eliminate the effects of a transit trade through Kenya, which is shown as receiving some £818,000 of produce from Tanganyika, including over £450,000 of coffee. If

these figures are adjusted in accordance with the most probable hypotheses, the exports of Tanganyika, excluding gold, would appear to go to the extent of some 21.1 per cent. to the United Kingdom, 33.4 per cent. to the rest of the British Empire, and 45.5 per cent. to foreign countries, of which approximately 10.9 per cent. is the share of Germany. In the case of South-West Africa, approximately 25.4 per cent. of exports went in 1934 to the United Kingdom, 28.3 per cent. to foreign countries, of which 20.4 per cent. went to Germany, and 46.3 per cent. to the rest of the British Empire, entirely accounted for by trade with the Union of South Africa. But the proportions in which exports from this territory have been divided between countries have been extremely variable. In 1929, when the export of diamonds was some sixty times greater than in 1934, and the export of copper ore, non-existent in 1934, yielded over £700,000, the United Kingdom received 47.4 per cent. of all exports, foreign countries 37.5 per cent., and the rest of the British Empire (in effect the Union) no more than 15.1 per cent.

If we turn now to non-British territories, the French colonies south of the Sahara sent to France 71.7 per cent. of their exports in 1934. This figure had increased substantially during recent years—in 1929 it was no more than 52.7 per cent.—and the share of foreign countries had declined proportionately, from 46.8 to 27.3 per cent. The trade between the various French colonies is inconsiderable, and at neither date exceeded 1 per cent. of the whole. The French share was highest in 1934 in French West Africa, where it was 78 per cent. of the whole. In French Equatorial Africa it was 64.8 per cent. It was lowest (apart from the unimportant trade of French Somaliland) in Togoland, where it was 47.3 per cent. The increased proportion of export trade with France was most noticeable in the case of French Equatorial Africa, where the French share had been only about 33 per cent. in 1929. The increase was considerable also in French West Africa and in the Cameroons. In Togoland and in French Somaliland there were decreases in the French share. In the case of the Belgian Congo 74.9 per cent. of exports was consigned to the mother country in 1934 as compared with 56.6 per cent. in 1929. But, as was noted above, the Belgian statistics indicate only the country of consignment and not of ultimate destination, and the figures

for other countries include consignments to Angola and Moçambique for further shipment, equal in 1934 to 8.8 per cent. of all exports. On a reasonable hypothesis regarding the division of these consignments, the share of Belgium would probably be not much below 80 per cent. in 1934. The export trade of Ruanda-Urundi was to the extent of approximately 85.7 per cent. with Belgium in 1934, as compared with 69.1 per cent. in 1929. The exports of the Portuguese colonies are to a less significant extent to the mother country. Angola in 1929 sent 37.9 per cent. to Portugal. In 1933 this figure had risen to 57.1 per cent. In the case of Moçambique, the colony and the company's area together sent 36.5 per cent. of the exports of local produce to Portugal in 1934.

There are considerable differences in the destinations of African exports, not only according to the nationality of the exporting territory, but also according to the nature of the product exported. Thus, of the groundnuts exported in 1934, about 40 per cent. originated in British and 60 per cent. in French territories. About 75 per cent. was consigned to France and only 5 per cent. to Great Britain. Of palm oil, 60 per cent. came from British, 23 per cent. from Belgian, and 13 per cent. from French territories. Of this, 39 per cent. went to Great Britain, 20 per cent. to Italy, 9 per cent. to France, and 5 per cent. to Germany. On the other hand, Germany took 31 per cent. of palm kernels and Holland 17 per cent. Of cotton, 32 per cent. went to India, 31 per cent. to Great Britain, 17 per cent. to Belgium. Of cocoa, Great Britain took only 20 per cent., though 82 per cent. was produced in British territories, while the United States took 27 per cent. and Germany 23 per cent. Of the sisal, Belgium took 34 per cent., though Belgian territories contributed a negligible share of the output, Britain only 27 per cent., though her possessions produced 82 per cent., and Germany 19 per cent. The ultimate distribution of African copper is not easy to calculate, since a large part is shown as consigned to Moçambique, Angola, and other African territories, without the indication of the final destination. A very rough calculation would suggest that in 1934 approximately 30 per cent. was sent to Great Britain, 26 per cent. to Germany, 23 per cent. to Belgium, and 3 per cent. to France. But, as was indicated above, further re-consignment almost certainly modifies even this result.

Important as is the trade with the mother country from the point of view of the African exporting territory, it remains nevertheless relatively unimportant in aggregate in the imports of the great imperial powers. Thus imports into Great Britain from British African dependencies other than the Union and South-West Africa accounted for no more than 2.0 per cent. of the value of all imports in 1934. In the case of France, both the absolute trade with French dependencies and its proportion of the whole has been increasing in recent years, but in 1934 it did not exceed 2.8 per cent., rising to 4.1 per cent. in 1935. The Belgian imports from the Congo accounted for 5.4 per cent. of all Belgian imports in 1934, and imports from the Portuguese possessions for 10.9 per cent. of all Portuguese imports in the same year. Imports from all African territories south of the Sahara, inclusive of the Union and South-West Africa, accounted for about 3.2 per cent. of the imports of the United Kingdom and 4.1 per cent. of the imports of Germany in 1934. In 1913 Germany derived 4.6 per cent. of all her imports from the whole African continent (2.9 per cent. from south of the Sahara), and 0.4 per cent. from her African colonies. In 1936 she took 6.9 per cent. of her imports from the whole continent and 0.5 per cent. from her former colonies. But once again it is necessary to distinguish the relative importance of Africa in individual products from its importance in the aggregate of all trade. In the case of Great Britain in 1936 about 99 per cent. of palm kernels and about 76 per cent. of unrefined palm oil, about 92 per cent. of cocoa, about 22 per cent. of copper, and about 15 per cent. of platinum, about 32 per cent. of merino wool and over 82 per cent. of mohair, about 51 per cent. of mahogany and 12 per cent. of walnut came from African sources, and in the majority of cases almost entirely from British territories.

Of German imports in 1936, some 34 per cent. of copper was shown as coming from African sources, and a further 20 per cent. from the entrepôt countries, Holland and Great Britain, some of which was almost certainly African. About 47 per cent. of manganese ores, about 31 per cent. of edible oils, about 16 per cent. of wool, and 3 per cent. of cotton was shown in the German customs statistics as imported from African countries.

V. THE SOURCES OF AFRICAN IMPORTS

If we turn next to African imports, here again the smallness of the total trade in comparison with that of the other great and densely populated continents must be emphasized. The imports of Africa south of the Sahara amounted in 1935 to no more than 3·4 per cent. of the world's recorded imports of merchandise, a figure slightly greater than that of Oceania, but scarcely more than half that of South and Central America. The imports of the Union of South Africa are predominant in the total. They accounted in 1935 for 68 per cent. of the imports of all British territories south of the Sahara. This is the result not merely of a greater European population, but also of larger consumption of imports per head than elsewhere, consequent in part upon a higher degree of industrial development. Thus in 1935 the value of imported goods per head of population in the Union was £8 12s. 10d. The only other territory with a figure that approached this was the very similar territory of Southern Rhodesia, with £4 8s. per head. Zanzibar followed with a figure of £3 1s. 7d. The Gambia, the Gold Coast, and Northern Rhodesia took between £2 and £2 10s. per head; Kenya, the Sudan, and Somaliland between 15s. and £1; and South-West Africa, Tanganyika, and Sierra Leone between 11s. and 12s. Finally Uganda, Nigeria, and Nyasaland took only between 7s. and 8s. per head.

The imports of the Union are as diverse as those of any other considerable territory. Iron and steel goods and manufactures accounted in 1935 for just over 25 per cent. of the whole. The second most important group of imports was that consisting of motor-cars, bicycles, &c., which amounted to 12·1 per cent. of the whole. Apparel of various descriptions followed with 8·1 per cent. Cotton piece-goods, which were 6·8 per cent. of the whole, and other articles of native consumption were considerable, but were overshadowed by these other items. The proportions of different imports are not widely different in Southern Rhodesia and in Kenya from those of the Union. In Northern Rhodesia (partly in consequence of industrial expansion) the proportion of iron and steel products, 35·9 per cent., has been the largest of any territory. In the Gold Coast, while iron and steel goods accounted for over

20 per cent. of the whole, goods for native consumption were relatively more important and cotton piece-goods accounted for 23.2 per cent. of the whole. Finally there is a group of territories, including Nigeria, Sierra Leone, and the Gambia on the West Coast, and Tanganyika, Nyasaland, and Uganda in East Africa, where the import of cotton piece-goods and other articles for native consumption are of predominant importance. Thus in Nigeria piece goods account for 32.5 per cent. of all imports and iron and steel for only 11.7 per cent.

Apart from the Union the largest markets for imported goods are provided by Nigeria and the Gold Coast, which in 1935 took 20.0 and 18.9 per cent. respectively of the imports into British territories other than the Union and South-West Africa, by Southern Rhodesia which took 14.2 per cent., and by the Sudan which took 12.7 per cent. of such imports. Kenya, Northern Rhodesia, and Tanganyika each received a little over 7 per cent., and Uganda about 4 per cent. of such imports. Nyasaland, Sierra Leone, Zanzibar, and the Gambia did not exceed 3 per cent.

The sources of these extremely diverse imports cannot here be analysed in detail. Of the whole value of imports into the British territories in 1934, approximately 46.5 per cent. came from the United Kingdom. The Union and South-West Africa in that year drew approximately 48.4 per cent. of all their imports, and the remaining British territories approximately 43.1 per cent., from the United Kingdom. In the case of the French territories approximately 44 per cent., in the case of the Belgian approximately 40 per cent., and in the case of the Portuguese 43.9 per cent., came from the respective mother countries. The proportions of imports coming from the mother country vary, however, substantially as between different products. In the case of imports of the main manufactures of iron and steel, and of machinery and implements, the share of British products in the imports of the British territories other than the Union and South-West Africa was in 1935 approximately 63.4 per cent., and in the case of those two territories approximately 52.3 per cent. In the case of cotton piece-goods the British share has been markedly different in different parts of Africa. In West Africa during the years 1926 to 1932 the proportion of imports, measured by yardage, that came from the United

Kingdom was year by year close to 90 per cent. of the whole. In 1933 the proportion fell to 76·1 per cent., and in 1934 to 63·5 per cent. Japanese imports had risen from 2·5 per cent. in 1932 to 18·5 per cent. in 1934. In that year quotas were imposed in all the West African colonies¹ upon imports of certain Japanese products. The methods of determination varied somewhat, but in each case the basis was the imports of the years 1927-31, before Japanese competition became acute.² In 1935 the British share of imports of piece goods had again risen to 81 per cent.

In East Africa the situation is, from a British point of view, far less satisfactory. The proportion of British imports of piece goods, as measured by yardage, had already by 1926 fallen below 30 per cent. of the whole. For the years 1927 to 1930 it stood slightly above 20 per cent., for the years 1931 to 1934 between 15 and 10 per cent., and in 1935 was no more than 9·6 per cent. In Nyasaland it was in that year less than 6 per cent. of the whole.

Not only the English, but also British Indian and American producers of cotton goods, have lost substantial markets in East Africa. In Kenya and Uganda, for example, in 1929 some 19 per cent. of imported cotton goods came from the United Kingdom, some 14 per cent. from British India, 13 per cent. from the United States, 11 per cent. from the Netherlands, and 39 per cent. from Japan. By 1935 just under 9 per cent. came from the United Kingdom, some 2 per cent. from British India, less than 1 per cent. from the Netherlands, and the United States imports had almost ceased; Japanese imports had risen to over 88 per cent. of the whole. In these East African territories protection cannot be freely applied, owing to the existence of treaty and other obligations which will be discussed in more detail below.

The Japanese competition is by no means confined to cotton piece goods. To take Kenya and Uganda once more as an example, Japanese imports in 1935 exceeded those of any other country, not only in silk, where Japan had always been predominant, but also in artificial silk, where her share was over 88 per cent. of the whole, in woollen tissues, in boots and shoes, in

¹ The quota did not apply to the mandated territories of British Togoland and Cameroons.

² See G. E. Hubbard, *Eastern Industrialization and its Effect on the West* (2nd ed.), 1938, pp. 19-21.

haberdashery, hosiery, in hats and caps, in umbrellas, in many sections of glass and china-ware, in cycle parts and accessories, and enamelled hollow-ware. Japan was the second largest source of imports, doing a substantial part of the whole trade, in toys, gramophones, lamps, cycle tubes, soap, and electric light bulbs. In 1934 over 22 per cent. of the imports into Tanganyika and Nyasaland, over 19 per cent. of imports into the Sudan, and over 15 per cent. of those into Kenya and Uganda came from Japan. The competition is felt almost equally in non-British territories. In the Congo some 10 per cent. of all imports was Japanese.

The problem of Japanese imports is not, of course, confined to the markets of Africa, and any full discussion of it would involve a general consideration of trade relations between Japan and other countries far wider than can be undertaken here. The entry of any new great manufacturing nation into the markets of the world must inevitably result in dislocations and readjustments which, however much they may benefit the world as a whole, will almost certainly do damage, temporarily or permanently, to those countries which previously enjoyed a large hold upon the markets invaded. But Japan has entered the world's markets not only as a seller but also as a buyer. From Great Britain and the British Empire she imported in 1936, according to the Japanese import statistics,¹ about £51,000,000 of goods, and exported to Great Britain and the British Empire about £41,000,000. Thus the British countries as a whole have a favourable balance of about £10,000,000. The large imports of Indian cotton, of Australian, New Zealand, and South African wool, of British machinery, and of rubber from the Straits Settlements, must be set against the exports of cotton and rayon goods, and a great variety of other manufactures. If the direct trade of the African countries south of the Sahara is considered in isolation, the exports of Japanese goods were shown in 1936 to be valued at about £6,900,000, and imports to Japan from the same territories at about £3,200,000. In 1936 Japanese imports from Kenya and Uganda, mainly cotton from Uganda, were almost equal to exports to those territories,

¹ See *Japan-Manchoukuo Yearbook*, 1938, pp. 478-80. The Japanese imports are, of course, valued inclusive of freight and insurance, and the exports exclusive of these, so that the relative total values of imports and exports will be somewhat different in Japan from those values at African ports.

according to values at the Japanese port. The Union's direct exports of wool covered about half the Union's imports of Japanese manufactures.

But quite apart from this dual aspect of Japanese economic activity, it must be remembered that Japan has succeeded in providing native buyers with the cheap goods that they have been able to afford. Whether this cheapness has been at the cost of a proportionate diminution of quality, it is by no means easy to judge. There is evidence to suggest that the preference for Japanese goods was in part a consequence of the decline of incomes consequent upon the depression, and it is possible that with increasing money incomes, demand may return to the better but more highly priced British goods. Thus during 1936 the proportion of Japanese goods imported into Kenya and Uganda has very slightly declined as compared with 1935. But the Japanese hold on the cotton piece-goods trade has become even more predominant. The British imports, measured in square yards, have fallen from 10.1 to 6.9 per cent. of those of Japan. It has been suggested that the admission of Japanese cheap goods may in the long run prove to be a less serious injury to British trade than might at first sight appear likely. It is in general true that higher standards of living result in an increase of imports per head, even if the proportion of the income spent upon them declines. In theory, therefore, anything that contributes to cheapen the necessities of native life might accelerate the adoption of European standards and provide a greater margin for the purchase of such minor luxuries as we are well fitted to supply. There are, however, many possibilities which may prevent this result, not the least of which is, that Japan may prove herself as capable of providing the minor luxuries of life as of capturing the market for piece goods.

Of countries other than the respective mother countries and Japan, those most concerned with African trade are Germany, and even in non-British territories, Great Britain. Germany's exports to the British African territories other than the Union and South-West Africa amounted in 1934 to a little over 5 per cent. of the whole. The proportion was highest in the mandated territory of Tanganyika, where it was about 9.8 per cent. of the whole; exports to Ruanda-Urundi were in the same year approximately

5·6 per cent. of the whole. The value of the total German exports to Tanganyika and Ruanda-Urundi combined was in 1934 approximately £245,000. It is of interest to compare this figure with that of approximately £1,264,000, the export of Germany to the same area in 1912. The German share of the trade to the whole of the pre-War colony has declined from 51·2 to 9·5 per cent. Similarly in 1912 Germany received approximately 56·6 per cent. of the exports of the combined territories. In 1934 she received only 8·0 per cent. of the exports of Tanganyika, and received no mention among the countries to which goods were consigned from Ruanda-Urundi, though indirectly certain goods may have reached her.

It is evident from the figures both for imports and for exports that the mother country enjoys in a large number of cases an advantage over other countries which, though varying greatly in its extent, is still on the whole sufficiently marked. It is of interest to attempt to judge what factors have been important in securing this advantage. In this connexion two questions will require consideration: first, how far the advantage may be due to the importance of government orders, and their general fulfilment from the mother country; second, how far fiscal and other devices have been employed to give preference to goods exported from the mother country.

Government orders are ordinarily more important in Africa, where so large a proportion of railway and other investment is commonly undertaken by the governments concerned, than they are in many other parts of the world. These orders have been analysed for two periods, first for the relatively prosperous years 1925-9, second for the years 1930-4, which, though not uniformly a period of depression in all African territories, were nevertheless years in which, in the majority of them, expenditure on railway extensions or on capital equipment generally was on a lower scale than in the earlier years. During the earlier period the government's share of the value of total imports (excluding sugar purchases for public sale) was as high as 24·4 per cent. in the Sudan. In the East African dependencies the figure was in the neighbourhood of 15 per cent., being highest in Kenya and Uganda, where it reached 18·4 per cent. of net imports. In Nyasaland and

Southern Rhodesia, where railways are not in government ownership, the percentage was only 1·8 and 3·7 per cent. respectively of net imports. In West Africa, government imports were of smaller relative importance than in the East. They were as high as 13·1 per cent. in Sierra Leone, but no more than 9·3 and 7·4 per cent. respectively in Nigeria and the Gold Coast. In the depression years the proportion has almost everywhere been lower. In the Sudan it has fallen to 17·5 per cent., in Kenya and Uganda to 10·8 per cent., and in the West Coast territories to a figure close in each case to 6·5 per cent. The purchases by the various governments of British territories are almost exclusively of goods from the United Kingdom or from other countries within the Empire. The exceptions would appear to be chiefly purchases of scientific instruments or of apparatus, that are best obtainable in Germany, the United States, or elsewhere. A similar analysis of government imports into non-British territories is not easy from existing statistical material. Moreover, in several instances, of which the Belgian Congo will provide an example, the dividing line between governmental and private enterprise is so ill-defined that any examination of the problem would be difficult. But there is no reason to think that the results would differ widely from those of the British territories. While the advantage of the mother country in the supply of material to the governments has been an important source of advantage, it is clear that it does not provide the complete explanation of the predominance of mother-country imports.

The use of the fiscal weapon to give a preference to the mother country in the import trade of African dependencies is less widespread than in other continents. The terms laid down by the League of Nations for the permanent mandates of Africa, as elsewhere, require that complete economic, industrial, and commercial equality shall be given to all nationals of states that are members of the League.¹ This sets an important limitation upon the granting of any form of preference in the mandated territories. It is generally agreed by the mandatory powers that under the terms of the mandate, there is no obligation on their part to maintain economic equality in the case of nations (as for instance Italy or

¹ *The Covenant of the League of Nations*, Article 22; *League of Nations, British Mandate for East Africa (Tanganyika Territory)*, Article 7.

Japan) which have left the League.¹ These countries continue, however, to enjoy the same status as before, in view of other treaties or agreements, such as those about to be mentioned, into which the mandatory powers have entered, in some cases before acceptance of the mandate. In the second place, the group of treaties commonly known as the Congo Basin Treaties preclude any form of preferential tariff in the areas to which they apply. The original treaty was signed in Berlin, on February 26, 1885, by Great Britain, Germany, Austria, Belgium, Denmark, Spain, France, Italy, Holland, Portugal, Russia, Norway, Sweden, and the United States of America. It was ratified by all save the last. No time limit was set to its operation. The treaty was concerned with far wider issues than the prevention of preferential tariffs. It dealt with important issues of equality, without respect of nation, in the exploitation of African resources, both in matters of industrial development and of individual settlement. It included declarations relating to the abolition of the slave trade, and the neutrality of these African territories in the event of war. It provided for the free navigation of the Niger and the Congo. These wider issues must be remembered in any discussion of the abrogation of the treaty, for in many respects it has been of immense benefit both to the development of Africa and to the position of investors in African territories. The original treaty provided for completely free trade within the area to which it applied. This was considerably wider than the Congo basin proper. It included an eastern extension to the Indian Ocean, bounded on the north by the fifth parallel of latitude meeting the sea in Italian Somaliland, on the south by an irregular line which runs north-eastward across Northern Rhodesia from the south-eastern boundary of the Belgian Congo to a point close to the common junction of Northern Rhodesia, Tanganyika, and Nyasaland, thence southwards along the western boundary of Nyasaland to the Zambesi, thence eastwards following the river to its mouth. Thus it includes the whole of Kenya, Uganda, Tanganyika, and Nyasaland, and a small and relatively unimportant corner of Northern Rhodesia, the whole of the Belgian Congo, a large part of French Equatorial Africa, and parts both of Portuguese East and West Africa.

¹ *Report to the League of Nations on Tanganyika Territory*, 1937, para. 46.

The original treaty was modified by various subsequent treaties, and in particular by that of Brussels, signed in 1890, which authorized the powers which had signed or acceded to the Treaty of Berlin to impose duties for revenue purposes, not to exceed 10 per cent. *ad valorem*, and without differential treatment or transit duties. The War of 1914-18 put an end to all treaties as between opposing belligerents, but left unaffected treaties between allied belligerents, or between belligerents and neutrals. A conference was therefore called at St. Germain-en-Laye in 1919 for the purpose of revising the Acts of Berlin and Brussels. The resulting convention, which now governs the trade of the Congo basin conventional zone, was ratified by Great Britain, Belgium, France, Japan, Portugal, and the United States. It provides that the signatory powers shall maintain between their respective nationals and those of states members of the League of Nations, which may adhere to the convention, a complete commercial equality in the area defined in the Act of Berlin. Since, except in regard to the schedule of arcas, the convention abrogates the Treaties of Berlin and of Brussels, the limitation of customs duties to 10 per cent. no longer applies, and the sole requirement is equality of treatment to nationals of all states. Thus in 1934 Kenya and Uganda changed their tariff from an *ad valorem* to an alternative specific and *ad valorem* basis. The complete equality of treatment has always been subject to one reservation. Portugal, at that time the only power possessing territory in the eastern extension, agreed to the free trade proposals only subject to the condition that they should apply to new acquisitions of territory and not to the existing Portuguese colony. This reservation was renewed at the Convention of St. Germain-en-Laye, and the Portuguese have always regarded themselves as free to impose differential duties, and they have in practice done so in certain cases.

The denunciation of the Congo Basin Treaties has been mooted on more than one occasion, and the recent growth of Japanese competition in the Congo basin area has led to a renewed demand that the countries which have spent their money in developing African territories should be permitted to enjoy some measure of preference in its trade, or at least that some revision of the boundaries of the zone should be permitted, so that it should be to a

greater degree continuous with present political units. No complete discussion of the merits and demerits of such a proposal can be here attempted. It is important, however, in any examination of the problem to remember that any general raising of tariff barriers within the African continent might in certain respects prove to be detrimental both to Great Britain and to the British Empire. British exports to non-British territories lying partly or wholly within the Congo basin zone are greater than imports of Japanese goods into British territories in the zone. There is in addition an important trade between the Union, the Rhodesias, and Kenya and Uganda on the one hand, and the non-British countries within the conventional zone on the other hand.

In the British areas unaffected by the Congo Basin Treaties, preference to British goods is sometimes prevented by treaties of more local application. In Nigeria any exclusively imperial preferential duties have been prohibited by the Anglo-French Convention of 1898;¹ the relevant article of the Convention has, however, been denounced by France, with effect from October 1936, and the tariff régime now to be adopted is under consideration. The same treaty has prevented imperial preferences in the Gold Coast,² but in both territories a system of quotas or additional duties has been applied (as was seen above) to imports of certain goods of Japanese origin. In Sierra Leone there are no similar limitations on the power to grant preferences. Import duties are partly on a specific, partly on an *ad valorem* basis. A preference of 10 per cent. is given to products of the British Empire in every case where a duty is payable.

In the Union of South Africa, as an outcome of the Imperial Conference held at Ottawa in 1932, the preferences previously extended to British goods have been abandoned in favour of specific trade agreements giving preference to goods which are the produce of the countries concerned. Such agreements have been entered into with Great Britain and Northern Ireland, Eire, and Canada, and are embodied in Act 8 of 1933. Under the tariff introduced in 1935, the duties imposed on different commodities are reckoned according to three separate scales, a minimum, an

¹ *An Economic Survey of the Colonial Empire, 1935*, p. 139.

² *Ibid.* 1933, p. 111.

intermediate, and a maximum. The minimum scale applies to imports from British countries with which trade agreements have been concluded; the intermediate scale to non-British countries with whom reciprocal trade agreements have been negotiated; the maximum scale in all cases in which an agreement to charge the minimum or intermediate scales has not been concluded. In addition, suspended duties and dumping duties enable protection to home industries to be increased when a protective duty has proved insufficient, or when as the result of policy, bounties, or exchange depreciation, goods are being sold in the home market at abnormally low prices.¹

The Southern and Northern Rhodesia customs tariffs were based on the Union tariff of 1925, and agreements were made between the three territories in 1930. Since 1931, however, there have been wide divergences in all three tariffs. In 1933 a new agreement was made between the Rhodesias, and in 1935 the previous agreement between Southern Rhodesia and the Union was terminated, and a number of changes were introduced in Southern Rhodesia which increased the duties on foreign and dominion goods and reduced duties on United Kingdom and colonial goods. Northern Rhodesia decided not to adopt the amended tariff, with the result that the differences in rates between the Northern Rhodesia and Union tariffs are not so great as those between Northern and Southern Rhodesia. The agreements provide for free entry or preferential treatment of the exports of the produce of one territory into the area of another, and for the refunding by the territory to which import duties have been paid of the duty levied on goods transferred to another territory. Certain restrictions, however, are placed on the free entry of agricultural produce from one territory to another. Since in practice a large part of the imports enter through South African ports, the Union Government pays annually to the Rhodesias a part of its customs revenue less 5 per cent. of the duty levied.

A more complete customs union exists between Kenya, Uganda, and Tanganyika, under which the produce and manufacture of any of the three territories are admitted free of duty into the consuming territory, and duty-paid goods may be transferred to any of

¹ Act 44 of 1935.

the other territories, but no preferential treatment can be given to British goods.¹

Some parts of the French territories fall inside the Congo basin zone, and preference is thereby debarred. Outside the Congo basin zone is a further area in which, in accordance with a convention of 1898 between Great Britain and France, no preference could formerly be given to French goods. In the free zone outside these convention zones, the French Government charge both a general duty and a surtax on dutiable goods of non-French origin. As was indicated above,² the French Government in 1935 suggested the suspension from October 1936 of the relevant article of the convention, and unified the customs systems of the two zones.

The Belgian Congo, lying entirely inside the Congo basin zone, has a tariff system that is partly specific, partly *ad valorem*. Cotton goods and blankets, despite Japanese competition, remain on an *ad valorem* basis. No preferences are given to Belgian producers.

In the Portuguese territories the duties are mainly on an *ad valorem* basis, but certain articles are subject to specific duties, and their number is being progressively increased. The latter include many foreign articles for the native trade, such as cotton goods, blankets, shoes, and native hoes. In addition to these duties, freedom of trade is limited by the existence of import and exchange restrictions. A decree of 1932 divided imports into Portuguese East Africa into two categories, prime necessities and luxuries, and permitted the purchase of the latter only after the requirements for exchange to buy necessities had been met. Quotas were fixed for individual categories of luxury goods, higher in most cases for Portuguese, lower for foreign goods, and ranging in 1936 from virtual prohibition to some 60 per cent. of the 1931 imports. In Moçambique Colony the limitations imposed by the Congo Basin Treaties do not affect the freedom to grant preference to the mother country and to other Portuguese colonies, and duties on foreign goods are in some cases from twice to five times those on Portuguese imports. Angola lies partly within, partly outside, the conventional basin of the Congo, and two scales of duties exist, one applicable

¹ See above, pp. 1340 ff.

² See above, p. 1343.

within, and the other, rather higher, outside the zone. Within it no preference exists at present for Portuguese goods. Outside there is a 60 per cent. reduction of duty on goods from Portugal and 50 per cent. on those from other Portuguese colonies, with a further 10 per cent. reduction for goods shipped in Portuguese ships. As in Moçambique, there have been restrictions since 1931 on dealings in foreign exchange. An exchange fund, replenished by receipts from customs duties payable in foreign currencies, by three-fourths of the value of all exports, and by any foreign currency received, is made available, first for government needs, secondly for dividends on foreign capital, and only finally, so far as funds permit, to buy imports. The effect has been to give a considerable measure of preference to Portuguese as compared with foreign products.

In some territories it is clear that the predominance of the mother-country trade can largely be explained by government purchases and fiscal preferences taken together. But in a considerable number of cases these are insufficient to explain the whole, or even a large part, of the advantage. It would appear that this must be found rather in such physical connexions between colony and mother country as are provided by the existence of regular steamship sailings, or more recently of direct air services; in the less tangible connexions which arise from a closer knowledge of the standing and reputation of firms and of the quality to be expected of their products, from the opportunity of dealing with concerns that speak the same language and are subject, in an emergency, to familiar processes of law, and from a natural preference for the goods of one's native country; finally in the advantages of making payments or entering into contracts in a currency that bears a fixed relation to the local currency.

This last advantage has been so widely canvassed that it needs further examination. Whether a country is buying goods from another using the same currency, or a different one, an import must be paid for by the importing country. The latter can only obtain the means to make the payment either from the sale of exports or from a change in its indebtedness to other countries. It may be somewhat easier for a mother country to buy imports from one of its dependencies, without an immediately countervailing

export, merely because the financial institutions of the two countries are better accustomed to being indebted to each other. In the particular case of sterling, it may be that exporters, having accepted the most commonly used international money, are more inclined to use it to buy British goods. But, this apart, in any longer period the greater ease of the mother country in buying imports must depend upon its greater ease in securing markets for its exports. Thus the advantage of a power possessing colonies, and the handicap of a country that lacks colonies, depend upon their comparative opportunities to expand their exports so that they may secure those imports which they need. Of the exports of mother countries, however, a large part is almost everywhere an export of capital goods, balanced not by immediate imports of raw materials, but by more distant promises to pay interest. In the very short run this export of capital goods does nothing to create countervailing exports to the mother country, but over a longer period it both creates facilities for the production of such exports, and an obligation to send them in order to provide interest payments on the earlier loan.

In a freely operating economic system it would be true to say that if any country set sufficient store upon colonial imports to be prepared to reduce its export prices to obtain them, it could do so. Whether in the existing situation a country can equally succeed in increasing its exports to obtain them is less easy to answer categorically. It has been argued that, in the face of duties and of the advantages of mother countries, the policy of lowering export prices, or lowering exchange rates which has the same result, has been tried and has proved unworkable.¹ Such a conclusion is difficult either to prove or to disprove. It is not impossible that, while a small change of export prices might be of little advantage, a considerably greater one would be highly effective. As we have seen, Japan appears to have been successful in increasing its trade with the African dependencies of other powers, while Germany has not. But any discussion of elasticities of demand is fraught with difficulties in a world in which quotas and restrictions are more important than relative costs of production. The problem of

¹ For the views of Dr. Schacht regarding this problem, see, e.g., S. H. Roberts, *The House that Hitler Built*, 1937, pp. 145-51.

colonial imports is indeed only a single aspect of a much wider problem of currency policies on the one hand, and of barriers to international trade on the other.

VI. THE BALANCE OF TRADE

The investment of capital in the development of African territories contemplates, it has been seen, the subsequent creation of an export surplus from which to provide for interest payments. It has been one of the difficulties of colonial territories to make the transition from the stage of investment, when imports tend to exceed exports, to the stage in which a sufficient export surplus exists to meet these charges. So long as foreign investment takes the form of actual dispatch of machinery or materials, no great problem is caused by its cessation. But not infrequently foreign investment takes the rather different form of providing temporarily the means to buy imported commodities for consumption, thus setting free individuals living within the territory to occupy themselves in the creation of capital works, such as roads, buildings, railway earthworks, cuttings and tunnels, or mining development. Where a country has come to depend upon an import surplus of consumable goods of this kind, the transition is likely to be considerably more difficult.

It is not easy to measure accurately the present investment from year to year in individual territories. Professor Frankel's calculations, based in the main upon public issues, are sufficiently trustworthy over long periods, but over shorter periods they are less reliable. For the actual investment, the creation of capital works, often precedes the public issue, and takes initially the form of private investment which cannot directly be measured. The most accurate indication of the volume of foreign investment is to be obtained from a calculation of the balance of payments of a territory.

A knowledge of the balance of payments is so necessary to any complete understanding of the situation of a country, that it is surprising that it has so rarely been calculated for African territories. Apart from the Union, where the figures are annually available, there have been only occasional attempts, such as that made by the Economic Development Committee of Kenya, to

make a calculation for one individual year. Few of these have been wholly successful, and most have suffered by the exclusion of some at least of the relevant data. But it should not be unreasonably difficult or onerous to collect sufficient information to provide a broad indication of the current state of affairs.

In the absence of more complete information it is of interest to calculate the visible surpluses of exports for certain territories and to compare them with the necessary home charges for debt and for pensions and gratuities. The debt charges include interest payments due from the railways as well as from the governments, and sinking fund as well as interest payments. The surplus of exports is calculated inclusive of movements in each direction of bullion and specie. To some extent this is unsatisfactory, since inward specie movements are in certain cases to be regarded as a consequence of a surplus of exports, or outward movements as one of a deficiency. On the other hand, where there is a continuous inflow of specie, that constitutes a normal import of the territory, and where there is a regular shipment of bullion from gold mines, that is a normal export of the territory. Since in most cases bullion movements are not distinguished from specie movements, and the normal inflow of specie is hard to determine, it is probably best to take the surplus of exports including specie movements.

The relation of the excess of exports to the fixed home charges on government account is, of course, only a broad indication of the industrial health of the territory concerned. On the credit side there must be added to the exports any receipts by persons resident in the territory of dividends or pensions or other remittances from abroad, any remittances by missionary societies or similar bodies, any expenditure by tourists or other non-residents. On the debit side, in addition to payments for imports and for home charges, there must be provision for leave pay, and for the homeward remittances of serving officials. What remains will then represent, in the absence of any current capital movements, the profits remitted abroad by private investors. If these are known it will be possible to calculate the inward or outward flow of capital.

There are a few territories which have had adverse balances of imports over exports in all except the most favourable years. Thus the Sudan had an average excess of imports of £1,006,000 for the

years 1915-30, partly explained by investment in the irrigation schemes. In 1932 the balance became favourable, and in 1936 there was an excess of £1,040,000 of exports to meet interest and other home charges. In most territories there has ordinarily been a favourable balance, though not always sufficiently large to cover the necessary home charges. In Tanganyika in 1934 the export surplus was about £367,000. The debt charges and pensions alone required in the same year about £453,000. In 1936 the surplus had risen to £1,341,000 and the same charges to about £521,000. In Nyasaland there was a surplus of exports of £268,000 in 1934, which had fallen in 1936 to £24,000, largely as the result of a big inflow of specie in the latter year. Debt and pension charges amounted to about £43,000 in 1934 and about £100,000 in 1936. In Northern Rhodesia the copper exports have provided an enormous export surplus, about £1,537,000 in 1934 and as much as £3,696,000 in 1936. Pensions and debt charges were about £165,000 and £184,000 in the two years.

In Kenya the position was closely scrutinized by the Economic Development Committee in 1935, who found some grounds for disquiet. The entrepôt trade of Kenya with Tanganyika and Uganda, and the common railway system shared with the latter, make Kenya's individual position peculiarly difficult to analyse. The figures of the majority and minority reports of the Committee differ slightly, but both are agreed in finding a visible adverse balance of about £3,000,000 in the years 1928-9, of about £1,300,000 in 1930, becoming slightly favourable in 1933. Debt and pensions charges would absorb about £1,250,000. Since 1933 there is little doubt that the position of Kenya has very considerably improved. If it is considered in conjunction with that of Uganda it would appear that in 1934 there was a joint export surplus of about £1,797,000, while their joint debt and pension charges amounted to about £1,403,000. In 1936 the surplus had risen to £3,169,000 and the home charges to £1,469,000.

It was pointed out above that the items which have been included do not exhaust the field of necessary remittances, and that a surplus is necessary also to cover leave pay and expenditure, and home remittances of serving officers. While these cannot be calculated with accuracy from any published statistics it is important to

form some idea of their probable magnitude. The total of personal emoluments, European and native, in the two territories was in 1934 £1,693,000. When allowance is made for the fact that certain reliefs take place at the end of a term of service, it would appear that about one-eighth of the personal emoluments is drawn in the more healthy territories by European officers on leave. This would require about £200,000 to be remitted. In addition, such officers almost certainly spend when on leave more than their current pay, in which case a 50 per cent. addition would make the total £300,000. Most officers also remit insurance premiums and sums for their families or dependants. Evidence would suggest that this may be in the more healthy territories about one-sixth of their pay—in the case of Kenya and Uganda some £250,000. These figures are admittedly, in the absence of the necessary statistical data, no more than speculative, but they may perhaps serve to show the order of magnitude of the export surplus necessary to meet these requirements. For the particular circumstances of Kenya, with a civil service, part of which is local and domiciled in the territory, and with the unusual local opportunities for education, the total of £550,000 may perhaps be somewhat too high. But in any year before 1936 it must be doubtful whether, even with a substantial inflow of investment income from abroad, the balance of trade was satisfactory except with the support of continuous capital investment.

The importance of these invisible items makes the calculation of a balance for the West African territories from existing data even more uncertain. Nigeria had an export surplus of £4,643,000 in 1934 and £2,891,000 in 1936. Debt and pension charges required about £2,063,000 in the first year and £2,120,000 in the latter, leaving a surplus when these had been met of £2,580,000 and £311,000 respectively. The total of personal emoluments was about £990,000 in 1934. Of this it is possible that as much as £600,000 is spent on leave and home remittances. Even thus a large surplus remained in 1934 to cover the profits of trading firms and other outward payments, but in 1936 there was almost certainly an adverse balance. The Gold Coast, with an export surplus of £3,269,000 in 1934 and £980,180 in 1936, and debts and pensions a little under £1,000,000, has probably in most years a safe

margin. Sierra Leone, with debt and pensions charges of about £157,000, and leave and remittance expenditures which may well be as high as £100,000, had in 1934 a surplus of only £207,000, but by 1936 this had risen to £1,030,250.

An adverse trade balance is not necessarily a sign of danger. A vigorous and rapidly developing territory in which current foreign investment exceeds the interest payments on the past investment will normally show a surplus of imports. Northern Rhodesia in 1931, at the height of the period of construction of the new copper mines, had an adverse visible balance of almost £5,000,000, when exports were still below £1,000,000. But in the absence of active investment it must be a matter for concern. Knowledge of the existence of an adverse balance may serve to forewarn an administration of a coming decline in imports and customs revenue, and of more general difficulties of industry and agriculture.

VII. STATISTICS

The Union of South Africa has a well-equipped Statistical Department, and Southern Rhodesia has commenced the organization of a statistical service. As a general rule, however, the full statistical data required to guide administrations in their economic policy are seldom available in Africa. A very high level of statistical perfection requires, there is no doubt, an expensive staff and meticulous accuracy of detailed work, such as is not easily obtained from African subordinates. Some territories have been led by a desire for economy to dispense with the services of a trained statistician or to refrain from appointing one. How far this is a true economy must depend upon local circumstances, but it must be remembered that the revenues and expenditures which have to be controlled are very large in comparison with the salary of such an official, and the difficulties of making satisfactory decisions in the absence of necessary information are, as the Kenya Economic Development Committee has indicated,¹ very great. But if the highest level of statistical perfection is unattainable, it is nearly always helpful to know the probable order of magnitude of the factors involved in some situation. An intelli-

¹ *Report of the Economic Development Committee, 1935, pp. 143-7.*

gent estimate, based on such evidence as may be made available at reasonable cost, will often provide a sufficient guidance for practical purposes, and is greatly to be preferred to none at all; but it must be an estimate made by one who is accustomed to deal with material of this nature. In the particular case of the balance of payments, the items that are sufficiently large to be worth considering could probably all be estimated within limits of probable error narrow enough to indicate whether or not administrative action of one kind or another was necessary.

The existing statistics of many of the territories might, however, in some respects be considerably improved without added expenditure. No useful purpose would be served by retailing here the many irritating deficiencies and inconsistencies which have been encountered during the preparation of these chapters; it is enough to say that eccentricity, so interesting in social life, loses its charm when applied to the compilation of trade statistics. More serious defects are concerned with conflict between the intentions announced in the explanatory notes of trade tables and their subsequent performances in the official blue books. This in particular affects the treatment of government imports. A problem that certainly requires careful consideration is that of the form in which the original data are made available to the general public in Colonial Reports and the Economic Survey of the Colonial Empire. In a number of the African territories the entrepôt trade is considerable. Thus the gross import figures may greatly overestimate local consumption, and an aggregate of import figures of a number of territories may count a by no means negligible proportion of the total imports more than once. It would be most valuable if the import and re-export tables could be combined for each territory to indicate the retained imports. Failing this, it would appear to be very desirable not to publish the import figures without making available also the re-export figures, and to modify figures of imports per head of population to show the net retained imports per head only, since the gross imports per head have no useful significance. These are, however, minor points, and there must always remain many pitfalls for an unwary reader,¹ such as

¹ See G. L. M. Clauson, 'Some Uses of Statistics in Colonial Administration', *Manchester Statistical Society's Journal*, Jan. 1937.

the difficulties involved in the valuation of exports produced by companies owned and controlled outside the territory.

In the non-British territories the chief difficulties of statistical analysis have arisen from the somewhat inconsistent indication of countries of immediate consignment of exports and of ultimate destination. Wherever knowledge of the ultimate destination is available, this is, from the point of view of every possible user of the statistics, the more valuable information, and even if occasional errors are involved, they almost certainly will not exceed those which must arise in any subsequent attempt to adjust countries of consignment so that they may indicate the ultimate destinations.

VIII. GENERAL CONCLUSIONS

These deficiencies of the statistics, however troublesome, are not sufficient to invalidate the general picture of Africa's present position in relation to the world economy. As compared with the thickly peopled continents of the northern temperate zone it is, and must for a long time remain, relatively unpopulated, and its share in world trade relatively small. Its progress and absorption into the world economy has been closely related to mineral discoveries. In their absence, capital investment in development projects has been risky and often unprofitable. In the absence of minerals, the great distances, small traffic, and high consequent capital and operating costs for consignment make transport costs heavy and agriculture relatively unprofitable, although in a few areas, especially on the West Coast, the combination of a more dense settlement and of a valuable cash-crop has brought comparative prosperity. Outside these areas both European and native derive from agriculture a subsistence which, though usually sufficient, is subject to many vicissitudes from climate, and from crop and animal pests. This continent, to a greater degree than almost any other, has relied upon foreign capital for its development, and it is of some interest to note the dominating position which British capital has taken in the process.¹ The inward flow still continues. It has helped to transform parts of Northern Rhodesia within the last decade. But it has not, save possibly in one or two instances, served to create an economy which is

¹ See S. H. Frankel, *op. cit.*, chap. i, pp. 16 ff.

dependent upon its continuance, and in many of the African territories the initial period of intake of capital is now replaced by an outflow of goods sufficient to meet the interest charges.

Save in respect of the Union of South Africa, it is not possible to forecast the time when any of the territories will be able to undertake the process, now well advanced in India, of converting its foreign obligations into internal debt, or of producing locally the capital required for further industrial development. If further capital is needed by these territories it must continue to come from outside; but it is not easy to estimate the demand which they are likely to make in this respect. The annual investment in Africa has, indeed, been greater during the last decade than during almost any other period, and new mineral discoveries may at any moment attract yet more capital. But, that apart, the development of the agricultural areas of Africa by railway building would appear almost to have reached finality at existing rates of interest, given the existing method of cultivation and the present state of development of world markets. The consideration of the abandonment of existing branches would even suggest that operating and depreciation costs, apart from capital charges, are, in some cases at least, beyond the capacity of existing or probable traffic. As has been suggested elsewhere,¹ there are, south of the Sudan, few irrigation projects of any magnitude which need financing by foreign capital, unless indeed experience of the scheme now approaching completion on the Niger² proves that other works of this description can profitably be undertaken in the same locality. It has been suggested³ that in these circumstances the proportion of equity capital investment is likely to increase, and that in the Union, in West Africa, and certain other areas there will be a further growth of such private capital investment as falls under the definition of 'non-listed' capital. There is, indeed, some ground for doubting whether the large increase in funded debt incurred by some of the colonial areas since the War has not created so high an interest charge as materially to restrict the possibility of their entering on fresh loan commitments. The British territories have increased their debt charges by 800 per cent. over the figure of

¹ See Chap. XV, pp. 1025-6.

² *Ibid.*, pp. 1049-51.

³ S. H. Frankel, *op. cit.*, chap. vi, pp. 421 ff.

1913. Between 1927 and 1934 the Belgian Congo increased its debt fourfold.¹ The character of the burden was fully appreciated during the recent period of depression; at such a time, the service of the public debt places a relatively higher burden on such funds as are available, since an increased proportion of the curtailed income of the state has to be sent abroad. An analysis of the public debt of the British colonies and protectorates shows that, while a large proportion of the expenditure against loan funds has been incurred on railways or other undertakings of a revenue-producing character, there remains a proportion which has been expended on road communications, buildings, health measures, or on the funding of revenue deficits. A considerable part of the expenditure against the French colonial loan of 300 milliard francs has been on road communications and similar objects, the loan having been explicitly linked up with the policy of *mise-en-valeur*.

There is, no doubt, much to be said for the orthodoxy of a government, like that of British India, which has so arranged its finances that the greater part of its public debt can be said to be secured on revenue-producing assets. It is at all events satisfactory that certain of the African administrations, whose revenues have been rehabilitated by the return to higher price-levels, have initiated a Revenue Reserve Fund, in order to meet the cost of development measures as far as possible from revenue, and thus avoid a resort to the loan market for expenditure of a technically 'unproductive' type. It is not necessarily contrary to the canons of good finance to incur 'unproductive' expenditure from loan funds; it is, for example, a common practice everywhere among local government bodies. The only test is that of ordinary prudence. Given conditions which are not unduly subject to climatic vicissitudes, and a population with an improving taxable capacity, expenditure of the 'unproductive' type can safely be incurred from loan funds, especially if it be on objects such as road communications, measures to control epidemic disease, or improvement in agricultural methods, which tend indirectly to improve the capacity of the taxpayer. But the recent period of depression proved that, with a few exceptions, the African colonial admini-

¹ S. H. Frankel, *op. cit.*, chap. v, p. 191.

strations could not be said to comply with these conditions.¹ Much of their customs revenue is derived from articles with which the native can readily dispense in time of scarcity or price depression;² and the direct tax on natives clearly does not lend itself to the rapid adjustments which may be needed in order to repair deficiencies in public finance.³ The economy of some of the governments is, moreover, so far linked up with the trade position of a single, or perhaps two, export crops,⁴ that their public finances must always be subject to hazards on which it is difficult to calculate. If, however, such administrations cannot properly look to loan funds for development expenditure, and must rely on their ordinary revenues for the purpose, it is obvious that their progress will be materially retarded. There are many who contend that the financial obligations of a colonial power towards an African dependency are not discharged by merely allowing it access, with or without a guarantee, to the money market of the home country; in their view, the real test of the faith of a colonial power in its capacity to improve the condition of a dependency is its willingness to give to the latter the financial support which it needs in its development. It is an obligation which was fully recognized by some of the colonial powers in the earlier days of their rule, as is shown by the extent of the contributions mentioned earlier in this chapter.⁵ Direct assistance is, however, now limited in the British territories to grants from the Colonial Development Fund, which are now given only for expenditure of an unusual type, such as would not ordinarily fall on the colonial budget; the subvention

¹ This problem has been discussed in relation to many African territories, notably by Sir Alan Pim for Kenya, *Report of the Commission to Enquire into and Report on the Financial Position and System of Taxation of Kenya*, Colonial 116, 1936, pp. 19-22, and for Northern Rhodesia, *Report of the Commission appointed to Enquire into the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, pp. 93-6 and 341; by Sir S. Armitage Smith for Tanganyika, *Financial Mission to Tanganyika*, Cmd. 4182, 1932, pp. 45-52; for South-West Africa in the *Report of the Commission on the Economic and Financial Relations between the Union of South Africa and the Mandated Territory of South-West Africa*, U.G. 16, 1935, pp. 34-5, 87, and 130-3; for the Belgian Congo by the Governor-General, M. Pierre Ryckmans, *Annuaire de documentation coloniale comparée*, 1936, vol. i, p. 11, and *La politique coloniale*, pp. 91-5; for French West Africa more briefly by M. de Coppet, *Discours prononcé par le Gouverneur Général à l'ouverture de la session du Conseil de Gouvernement*, Dec. 1936, p. 28. See also, S. H. Frankel, *op. cit.*, *passim*.

² The customs revenue of the British territories in Africa, excepting South Africa and South-West Africa, fell from £10,773,000 in 1929 to £7,217,000 in 1931. (S. H. Frankel, *op. cit.*, Table 39).

⁵ See above, pp. 1317-21.

given by Belgium to the Congo Government was designed as a temporary measure in order to repair some of the losses caused to the colony by the depression.¹ It is not unreasonable to hold that there are certain types of expenditure, such as communications, the provision of water supply or of health services, in which a colony with inadequate resources of its own might look for some definite assistance from the funds of the colonial power. As an alternative to a direct grant, it might be feasible to consider the making of a loan free of interest for a term of years, subject to further consideration as regards interest at the end of that period, such as those made by the British Government to Tanganyika. It has been suggested in the course of this chapter that the terms on which loans have been obtained by certain of the African dependencies, particularly in the period following the War, were such as to bear unduly hardly on their finances. There is some ground for feeling that not only this question, but that relating to the principles which should regulate the relations of the colonial power and its dependencies in the matter of grants for assistance towards the ordinary expenditure on development, should receive a more comprehensive examination than has yet been given to them.

¹ See Chap. XX, p. 1454.

CHAPTER XX

THE INTERNAL ASPECT OF AFRICAN ECONOMIC DEVELOPMENT

I. INTRODUCTION

THE preceding chapter was concerned with the economic development of Africa in its external aspect. The present chapter is concerned with the internal economic problems set in motion by capitalistic development, by the creation of new facilities for transport, and by the introduction of new techniques and new tastes.

It has been common, in studying problems of economic change in Africa, to distinguish two general types of organization: the original primitive economy on the one hand, and the new European capitalistic economy on the other. While for many purposes this broad distinction will suffice, in any attempt at a detailed examination of individual territories it becomes apparent that this simple dichotomy is an over-simplification of the many complexities of the actual inter-relations of the new and the old. It will perhaps help to clarify these relations if the various forms in which the European may collaborate with the native are first briefly considered. The European may provide the knowledge of the technique of production; he may provide the organization, discipline, and control; he may provide the capital necessary for equipment and works, for carrying finished or unfinished stocks, or for financing growing crops; he may provide the skilled operation of certain processes beyond the present capacity, at least, of the African native worker; he may provide marketing facilities for native crops or products; he may provide transport facilities for carrying native goods to their places of sale or consumption. Quite obviously the economic systems of Africa do not divide themselves into those in which the European performs all these functions and those in which he performs none of them. In many of the areas in which a casual commentator might say that the primitive economy still prevailed, Europeans will in fact be found to provide transport facilities, marketing facilities, and capital for carrying goods while in

process of being marketed, and thus to be modifying in greater or less degree the purely primitive economy.

As indicating broadly the form and extent of European penetration into the economic system, it may thus be convenient to distinguish five general types of economy discoverable in Africa to-day. The first is that of the Union, outside its native reserves, and of certain parts of the Rhodesias, Kenya, Tanganyika Territory, and Nyasaland, where permanent European settlers own and occupy land, while Europeans or Asiatics largely operate the main industries, and the activity of the native is limited to that of providing unskilled or occasionally semi-skilled labour. The second type of economy is distinguishable from the first only by the permanence and proportion of the European population. It is that which is associated with mining in many parts of Africa, even outside the areas of settlement. It is associated in certain territories also with the production of plantation crops. The European provides capital, technical management and organization, and marketing and transportation. The native performs such tasks of skilled and unskilled labour as may be within his capacity. In the third type of economy the European provides capital, transportation, marketing, and possibly certain preparatory processes; the native is responsible, possibly under some supervision, for primary production. Examples of this type of organization may be discovered in the Gezira scheme of the Sudan Plantations Syndicate, or in the irrigated areas of the Niger in French West Africa.¹ Fourthly may be distinguished the type of economy in which the native population undertakes and finances the primary production without any consistent non-native supervision, and the non-native's functions are confined to the marketing and transportation of his products. Such, for example, would be the case with the production of cotton in Uganda, or cocoa in the Gold Coast. In some instances, through native-owned lorries and native-controlled co-operatives, the contribution of the European to the trade within Africa itself may be reduced to relatively small dimensions. Finally there is the primitive subsistence economy, modified only so far as peace, taxation, and the growth of new wants have enforced change.

¹ See Chap. XV, pp. 1049-51 and 1053-5.

II. THE EUROPEAN ECONOMY

(a) *The Union of South Africa and the High Commission Territories*

Since the development of the modern economy, more particularly as regards the permanent settlement of Europeans and the ownership by them of a large part of the land, has proceeded further in the Union of South Africa than elsewhere,¹ and lessons derived from its experience may be applicable to existing situations in other territories, it is convenient to start from an examination of its problems. The difficulties both of a theoretical study and of the practical economic administration of the Union and the surrounding territories arise largely from the fact that it is not one single homogeneous economic system, but what may, indeed, be described as two systems, whose mutual relations are indefinite and progressively changing, and which cover areas that are not easy to define. Economic boundaries are by no means so coincident with political boundaries in Africa as they are to-day in Europe. Labour, in particular, moves with comparatively little impediment from one territory to another, and these relatively undeveloped units are more closely interdependent both for manufactures and foodstuffs than are adjacent countries in the longer-settled and more densely populated parts of the world. But for practical purposes it is convenient to treat them separately so far as that is consistent with reality. For the moment we shall be concerned only with the Union of South Africa itself and with the High Commission Territories, which lie within or are adjacent to its borders.

Within this area there exist concurrently one economic system that has predominantly European characteristics, though by no means exclusively a European personnel, and a second economic system originally with native characteristics, though in process of modification by contacts with the European. While the European system is in the main single and homogeneous, the native system is rather composed of a number of almost independent geographical units not very closely related to each other. Though these two systems are analytically distinct, individual natives move frequently from one system to the other. It is with the extent and

¹ See Chap. XII, pp. 814 ff.

causes of such movement that any study of the economy of South Africa must be primarily concerned.

The dimensions of the European system are not easy to state with accuracy. In the chapter dealing with labour, reference was made to the estimate made by Professor Grosskopf for the census year 1921, in which he calculated that some 856,000 natives were occupied in the modern economic life of South Africa.¹ Until the detailed results of the 1936 census are available, no exact calculation of recent growth is possible, but during those fifteen years the number of male natives resident in urban areas has increased by 95 per cent., of those occupied in industry by about 28 per cent., in mining by about 46 per cent.; in agricultural work the number had apparently risen by 1930, when the last available census of agricultural labour was made, by about 20 per cent.² An estimate based on such figures as are available would suggest that the number of natives occupied in the European economic system in 1936 was approximately 1,250,000. This must not be regarded as implying that any such number have finally severed all connexion with the primitive economy. The figure includes a very large number of natives who are no more than temporarily engaged in various occupations. But when they return to their homes, their places will be filled by others and the proportions of those occupied in the two systems will not be materially altered. The figure of those engaged in the modern economic life of South Africa includes all those natives from other territories who were working in the Union at the time of the census. Of these there were some 92,000 at the end of 1935 working in Kimberley and in the Rand labour districts alone. The number of women engaged in industry proper, as apart from those employed in domestic service or on farms, is probably negligible.

Apart from the Bantu there are two other groups associated with the Europeans in the modern economic system, the Asiatic population, concentrated chiefly in Natal, and the coloured population, concentrated chiefly in the Cape. In 1921 the total Asiatic population of 165,731 included 57,403 males over 18 years of age. Of

¹ See Chap. XI, p. 606.

² Some caution is needed in combining figures derived in one case from the population census of 1921, and in the other from the agricultural census of 1930. A part of the growth is possibly explained by a difference of classification.

these 19,478 were occupied in agriculture, 12,046 in commerce, and 6,066 in personal service. The coloured population, numbering in all 545,548, included 143,713 males over the age of 18. Of these almost exactly half were occupied in agriculture. The building and allied trades gave employment to 8,260, and personal service to another 8,988. Coloured girls have also found employment in large numbers. A little over 50,000 were occupied in domestic service; small numbers were engaged in industrial occupations, some 1,400 being employed in the clothing trades.

During the period 1921-36 both these sections of the population have considerably increased in numbers. The number of Asiatic males, largely as a result of immigration, has increased by 47.29 per cent., and that of coloured males by 41.15 per cent., in comparison with an increase of native males of 41.83 per cent. and of European males of 33.68 per cent. But whereas the coloured rural male population had increased by only 19.7 per cent., the urban had increased by 69.2 per cent.; and while the Asiatic rural male population had declined by 38.6 per cent., the urban had increased by 141.4 per cent. The numbers employed in factories have in neither case shown any marked increase, and in recent years have, indeed, tended to decline slightly. It would appear, therefore, that they have been absorbed partly by commerce, partly by personal service, and partly by occupations not covered by the industrial census.

In the year 1921, then, some 453,000 European males over the age of 18 were associated in the modern economic system with some 856,000 natives, 144,000 coloured, and 57,000 Asiatics, approximately 1,510,000 in all. By 1936 some 638,000 Europeans were associated, according to the foregoing estimates, with some 1,250,000 natives, 200,000 coloured, and 72,000 Asiatics, approximately 2,160,000 in all.¹ Thus the modern system had grown as regards the numbers of persons dependent upon it by about 43 per cent. during the fifteen years, that is by almost 3 per cent. per annum.

Though there has been no very marked change in the proportions of the four racial groups concerned, this rapid growth of activity in the modern economic system has inevitably thrown

¹ See Chap. XI, p. 606.

great strains upon all the various participants in it. In particular the balance between agriculture and industry has been disturbed. There has, it is true, been a very marked increase in the total of agricultural production. The area under cultivation increased by about 38 per cent., and the volume of exports of agricultural produce by about 41 per cent., between 1921 and 1935. But South Africa has shared during this period in the general depression that has affected agriculture throughout the world, and has suffered peculiar troubles of her own through drought and disease. Thus the prices of agricultural exports, which in 1920 had been 209 per cent. above the average of 1909-13, had fallen in 1921 to about 21 per cent. above that of those years, and after a recovery during the years 1923-9, sank in 1930 below the average of 1909-13, reaching a bottom point of 40 per cent. below in 1932. Thus, despite the general growth of agriculture, farming as a whole was less able than it had been in the past to support either a working or a dependent population which was not making an economic contribution equivalent to its cost, and individual farmers were driven into bankruptcy and poverty. The inevitable result was a drift to the towns of many hundreds of persons who were ill fitted both by character and training for the conditions of town life and the struggle to earn a living in industry or commerce.¹

The decline of agricultural prosperity was doubly important because of the very large part that it had always played in South African economic and political life. Until the discovery of diamonds in 1867 the economic development had been almost exclusively agricultural. The mining enterprises of the following years were in many respects a foreign growth. To the older agricultural population they afforded at first markets, rather than fresh occupations. During the subsequent half-century the earlier racial division between town and country dwellers, never by any means complete, has largely disappeared. But even at the 1926 census 61·3 per cent. of males of Dutch South African parentage were to be found in rural areas, and no more than 38·7 per cent. in urban areas, while of those of British stock only 20·8 per cent. were living in rural areas, and as many as 79·2 per cent. in urban areas. Though persons of Dutch South African parentage accounted for

¹ See Chap. XI, pp. 684 ff.

56.9 per cent. of the whole population, they accounted for slightly under 30 per cent. of the population of Johannesburg and the neighbouring Rand towns. Thus one at least of the two stocks which provide the majority of the white population remains even to-day predominantly rural and agricultural, and over large areas the other also is vitally concerned with agricultural occupations.

Agriculture is, moreover, by far the greatest single industry of the country. At the 1926 census, of 559,754 European males in different occupations, 172,643, just over 30 per cent., were occupied in agriculture. Mining gave employment to only 22,434. Transport, commerce, mining, building, and metal-working together employed fewer than did agriculture alone. The drift of the agricultural population to the towns, and the associated 'poor white' problem, has therefore been a matter of grave concern to successive administrations in the Union. The investigations of the commission financed by the Carnegie Corporation, to which detailed reference has been made in the chapter on labour,¹ would seem to show that the poor whites may be said to represent a population group of about 220,000 persons; the migration to the towns has been the consequence of lack of opportunity for employment in rural areas rather than of its existence in urban areas. Moreover, the majority of those who found their way to the towns were entirely unfitted for occupation in the urban industries.

The natural inclination to treat the growth of a class of poor whites as an agricultural problem, and to diminish the movement to the towns, has been reinforced by a recognition of the wasting nature of the mining resources upon which much of the national prosperity has been built. It was calculated by the Low Grade Ore Commission of 1930, with the assistance of Professor Frankel, that about one-half of the population of the Union was at that date supported by the gold-mining industry of the Witwatersrand, and that about half the government finances of the Union were derived, directly or indirectly, from it.² While the basis of this calculation has been criticized in detail, the main conclusion regarding the importance of gold mining to the whole economic structure of the

¹ *Report of the Carnegie Commission on the Poor White Problem in South Africa*, 1932, part i; and see Chap. XI, p. 685.

² See S. H. Frankel, *Capital Investment in Africa*, 1938, chap. iv, p. 115.

country cannot be called in question. Yet in 1930 the estimated reserves of the thirty-one producing mines and three developing mines, that were members of the Chamber of Mines, were only equal to about eleven years' output at the then current rate. The whole basis of the economic life both of the wealthier sections of the white population and of the poverty-stricken native reserves was threatened, and the most lucrative market of the agricultural population was in danger of collapse.¹

The abandonment by the Union of the traditional gold standard in 1932, and the rise in the price of gold, partly consequent upon that, partly upon the devaluation of gold-standard currencies, have now fundamentally changed the situation. The life of existing mines has been greatly prolonged, and in addition extensive new areas have been surveyed and developed. Moreover, the method of taxation of the mines has been so calculated as to encourage the mining of low-grade ores to a greater extent than can probably be justified by the maximization of immediate profits, though such a policy of preferring future to present benefits may well be regarded as legitimate in the circumstances of a nation living by the exploitation of wasting assets. No satisfactory estimate of the life of the gold mines is available, or indeed possible, in the new conditions. It has undoubtedly been very greatly extended, and the threat of early collapse has certainly been removed. But though the immediate urgency of the problem may be much diminished, it remains true that the economic system is largely built upon an asset with a terminable life, and if even a century of respite is granted, that is not long in the history of a nation. The encouragement of other forms of industry, the mining of base metals, the development of agriculture, can now be more deliberately and systematically pursued in preparation for the time when South Africa will no longer be able to depend upon the rapid exploitation of a mineral for which the world has hitherto afforded an insatiable demand, and which is hampered in international commerce by far fewer obstacles than is any other product.

These motives have led to attempts to deal with the poor-white problem at the source, by making agriculture more profitable and

¹ For a further discussion of the gold-mining industry see Chap. XXII, pp. 1487 ff.

more able to support both workers and dependents. The methods employed have been various. A Land and Agricultural Bank had been established in 1912 to facilitate the supply of capital both to individual farmers and to agricultural co-operative societies.¹ Loans may be obtained for improvements, for the purchase of stock, for the establishment of rural industries, for fencing, water supply, and various other purposes. The total advances made by the Bank amounted at the end of 1934 to about £15,000,000, more than nine-tenths of which was advanced to individuals. The Bank has been used from time to time by the Union Government as an agency for the distribution of relief to distressed farmers. In 1924 advances amounting to about £418,000 were made to farmers who lost stock or crops through drought. Within the following ten years all save about £30,000 had been repaid. Similar advances were made in 1927, and special advances to tenant and to landless farmers in 1926, 1930, and 1933. In addition to the facilities provided by the Bank special loans have been made available for farmers during the recent depression. An Act of 1931 provided means to farmers of meeting pressing liabilities through borrowing from a board created for the purpose, either by mortgaging land or by hypothecating crops or stocks. During the following three years over £4,000,000 were borrowed from the board at a rate of 5 per cent. per annum.

An Export Subsidies Act was passed in 1931 to mitigate the effects of competition from countries with depreciated exchanges before the Union itself left the gold standard, and to diminish competition in the more profitable home market and improve prices there by encouraging the export of agricultural products. This, with subsequent amendments, permitted a subsidy not exceeding 25 per cent. (or in the case of beef and mutton 35 per cent.) of the f.o.b. price of the product. By the end of 1935 no less than ninety-six primary products were covered. The actual subsidies paid were in many cases below the permitted maximum. The subsidies have been progressively reduced since 1935 and were finally discontinued at the end of 1937. In all some £10,000,000 had been paid out up to the end of August 1936. Of this almost exactly half was accounted for by a subsidy on wool exports, fixed originally

¹ See Chap. XII, pp. 815 ff.; Chap. XXI, p. 1468.

at 25 per cent. Citrus and deciduous fruit had received a little short of £2,000,000, while on meat less than £250,000 had been disbursed.

In addition to these export subsidies paid by the Union Government there have been, in the case of several primary products, export bounties, administered by control or advisory boards, and financed out of levies imposed upon all producers. Control Boards were created for the live-stock and wheat industries, for the dairy industry, for maize, wheat, and tobacco, and advisory boards for wool, hides and skins, and eggs. Export bounties have been paid on slaughter stock, butter, and cheese. The funds of the other boards have been used to create marketing, advertising, and research organizations. In the case of maize, an export quota percentage has been fixed annually, and every trader has been required to provide for the export of a quantity of maize equal to that percentage of his purchases.

Finally, in 1936, there was introduced a Marketing Act designed to establish a unified system of agricultural marketing in all the various branches of agriculture. Under the supervision of a Marketing Council and of the Minister of Agriculture, control boards for separate products are empowered to buy and sell produce, and thus control internal distribution and export, to fix quotas and prices, determine standards of quality, and regulate inspection and grading. Most of the earlier control boards have been reorganized in order to take advantage of the provisions of this Act.

Apart from these more direct forms of assistance to farmers, the railway rates, which have always been framed to help the agricultural community, have in recent years been further adjusted to cheapen the shipment of live-stock and of dead chilled meat, and more recently of wool and fresh fruit. The government has undertaken to refund to the Railway Administration the cost of the rebate.

By such means the condition of the farming population has been considerably improved, and the drift to the towns somewhat diminished. But there has remained a serious problem of urban European unemployment. It has been sought to mitigate this, partly by providing relief works, partly by encouraging the use

of European rather than native unskilled labour in certain employments.¹ The effects of this policy were discussed by the Economic and Wage Commission of 1925. The General Manager of the South African Railways and Harbours, in evidence submitted to that Commission,² claimed that the policy was justified in that 'thousands of men who would otherwise have drifted into the ranks of the irreclaimable have been able to regain a place amongst the self-supporting and self-respecting sections of the community'. He was not prepared to state precisely how much extra cost was imposed upon the Railway Administration by the employment of white labour. While in general terms it could be said that white employees cost about twice as much and were some 15 per cent. more efficient than natives, it was obviously necessary in many cases to replace one native by one European. But the amount of supervision required was less.

This 'civilized labour' policy³ has been criticized, both by those who have regarded it as an impediment to the most economical employment of African resources, and by those who have been concerned with the limitations that it has imposed upon the welfare of the native population. But no judgment of it is possible, unless certain fundamentals of South African economic development have first been postulated. A policy that is 'uneconomic', if the end in view is the maximization of the welfare of a single and unified economy of both native and European populations, may be 'economic' if the end is the growth of a primarily white community. The practical issues that led to the formulation of the policy were those arising from the competition of unskilled white labour with native labour, prepared to accept almost indefinitely low wages, since even so their circumstances were no worse than they would be in the poorer of the native areas. The white community was prepared to say, as other communities have said with regard to unemployed persons, that there was a minimum standard below which it was not willing to see unskilled fellow whites fall. It might have

¹ See Chap. XI, p. 685. It has been stated that while the European staff of the railways had risen from 39,024 in 1924 to 48,856 in 1935, the non-European regular staff had fallen from 47,157 to 19,923; see W. M. Macmillan, *Complex South Africa*, 1930, p. 109, and *Official Year Book of the Union of South Africa*, 1937, p. 499.

² *Report of the Economic and Wage Commission (1925)*, U.G. 14, 1926, para. 163.

³ See Chap. XI, pp. 682 ff.

said that if work were not forthcoming at that wage it would grant unemployment benefit. It has preferred to say that certain types of work should be reserved to white unskilled workers. Granted the assumption that white labour should not be permitted to descend to the level of income dictated by its efficiency compared with that of native labour, it is difficult to argue that such a policy is obviously 'uneconomic'. It involves the community, it is true, in expenditure greater than if it employed native labour and allowed its white unemployed to starve. It is by no means clear that it involves the community in greater expenditure than if it made the minimum practicable provision for its white unemployed.

But though there may be both political and theoretical justifications for the adoption of a civilized labour policy, its necessity must nevertheless be regretted. It is, of course, generally true that, except for short periods, employers will not continue to employ workers unless the value that they contribute to saleable products exceeds the wage which they demand. The value of the work of the unskilled white worker has been limited not only by the market value of the final product, but also by the share of it that has been demanded by more skilled European workers. Making use of a strong bargaining position, the more skilled workers have been able to secure for themselves a disproportionate share of the whole product at the expense both of the less skilled Europeans and of native workers.

It has been frequently pointed out, and in particular by the Economic and Wage Commission of 1925, that the spread of wages in the Union is very wide, both within an industry and between one industry and another.¹ The ratio of skilled to unskilled wages varied, they found, according to trade and locality from about eight to one to about three to one. In England the ratio was, and still is, approximately fourteen to ten in building and engineering, and not widely different in other industries. This high level of skilled wages cannot be explained by greater productive capacity or by the high level of the total income of the country. Real wages of adult European workers in the building industry

¹ For some examples of this see Chap. XI, p. 683. The Commission showed that in a given occupation the customary wages of local artisans in many country towns have been one-half of the ruling wages in the chief towns, *Report*, op. cit., U.G. 14, 1926, pp. 12 and 260.

were calculated to be higher than those in Australia in two of the five years 1929-33, higher than those in New Zealand in all five years, higher than those in the United Kingdom in all years by amounts varying between 17 and 29 per cent.¹ They were in 1925 (and the changes in more recent years have not been so great as to invalidate the comparison) some 55 to 65 per cent. higher than real wages in Berlin, Brussels, or Paris.² It was the opinion both of the majority of the Economic and Wage Commission of 1925³ and of the Customs Tariff Commission of 1934-5⁴ that real wages in South Africa were high relatively to the country's capacity to pay wages. The Economic and Wage Commission estimated the value of the total income of European industry and agriculture in 1923 at a little under £180,000,000. A reasonable estimate of the number of natives dependent upon it (2,900,000 out of 4,700,000) would make the income per head of *all* persons (as distinct from occupied persons) about £35. The comparable figures for Canada and Australia at about the same date were £100 and £78, for the United Kingdom about £80, and for France and Germany about £45 and £52 respectively. It would seem clear, therefore, that the exceptionally high wages of skilled craftsmen are derived not from a high general level of production, but from the opportunity that has existed in South Africa for that class to raise their own incomes by depressing those of others. The classes that have suffered have been, beyond question, the unskilled Europeans and the natives.

But the effects have not been confined to a distribution of wealth markedly different from that in most other countries. The high rates of wages that have been demanded by skilled labour and enforced partly by trade-union bargaining, partly by the awards of the Union Wage Board, have made it difficult for South African secondary industries to compete with imported products, except where the natural protection of high transport costs or perishability is great, or where actual protective duties have been imposed by the government and have checked or delayed the growth of other employment.

¹ *Official Year Book of the Union of South Africa*, No. 17, 1934-5, p. 203.

² *Report*, op. cit., U.G. 14, 1926, p. 27.

³ *Ibid.*, p. 34 et passim.

⁴ *Report of the Customs Tariff Commission, 1934-5*, U.G. 5, 1936, para. 346.

In the absence of protection in some form or another, South African imports must necessarily have been limited to that volume for which the country could pay with the products of those export industries, more particularly gold, diamonds, and certain branches of agriculture, which could survive in the face of the high level of local costs. Any uneconomic rise of wage-rates would result in unemployment in South Africa, and a consequent diminution of incomes, until the imports had again been brought within the limits set by South Africa's capacity to pay.

The economic system was thus condemned to run at half-pressure so long as South African wages were maintained at too high a relative level. The consequent unemployment took, however, a somewhat different form from that which it would take in a European country. The white workers who might in other circumstances have been employed in skilled and supervisory tasks have been forced to content themselves with less highly paid posts. The unskilled Europeans have been forced into more intense competition with native labour. The native labour displaced by this competition, and by the civilized labour policy consequent upon it, has been thrown back upon its own resources, and thus upon the production of its own native agriculture in the reserves.

Relief from this situation could be secured by several alternative means—by adjustment of wages, by currency depreciation, by a system of protection which would permit a higher level of internal wages and prices relatively to those of other countries, and by such reorganization as would increase the country's wage-paying capacity sufficiently to make the existing level of wages economically possible. The first two courses were for political and other reasons difficult to contemplate; the last, though by common consent desirable, would perhaps have placed an undue strain upon industrial and individual adaptability. Many observers would, nevertheless, have welcomed a greater reliance upon it. In the circumstances political pressure for protective duties was inevitable. In 1924 enlarged responsibilities were imposed upon the Board of Trade and Industries in regard to advising the government in matters of assistance to South African secondary industries, and in 1925 a revised tariff was introduced,¹ which, though historically an outgrowth

¹ *Official Year Book*, op. cit., No. 17, 1934-5, p. 617.

of the 1914 tariff, marks the beginning of a more distinct and purposeful attempt on the part of government to encourage the development of industry through the means of the customs tariff without, however, sacrificing the revenue consideration.¹ The declared objects of the tariff of 1925, as further amended in 1935, can be summarized briefly as being the assistance of already existing South African industries which, without such help, could not survive, so that they might develop into efficient and economic undertakings giving employment to increased numbers of persons on a civilized standard of living. They were to be industries, so far as possible, using local raw materials for manufacture into local consumption goods, or they were to be industries processing local export products, if such processing improved the position of the primary producers. So far as possible, duties were not to be imposed which would increase the costs of production of primary producers, more especially in mining or agriculture. Additional provision was made for protection against exchange dumping.

The success of this policy was examined by a Customs Tariff Commission of 1934. It reported that, to the best of its capacity to estimate, protection had given direct employment to some 26,000-28,000 Europeans and 21,000-23,000 non-Europeans. The further effects are more difficult to assess. If South Africa had enjoyed a full measure of employment, the growth of employment in the protected industries could be secured only by an equivalent contraction in other industries, and would imply a diversion of resources from more profitable to less profitable uses, which could be justified only on the ground that, by protecting certain industries, long-run benefits could be achieved which would outweigh the short-run losses. But in the existing circumstances of South Africa it was by no means clear that protection in every case implied a mis-direction of resources. If money wages were higher than production justified, recovery was, it has been seen, possible either by lowering wages or alternatively by raising prices without raising wages. Protection made possible a rise of local prices as an alternative to the reduction of wages. But it threw a heavy burden on many of the exporting industries. The gold-mining industry

¹ Memorandum submitted by the Board of Trade and Industries to the Tariff Commission, 1934, *Report of the Customs Tariff Commission 1934-35*, p. 115.

had in any case been helped by the change in the world price of gold, and while the existing level of South African costs somewhat diminished its capacity to give employment, it was not driven into such difficulties as other exporting industries. But agriculture required and received assistance in the form of export bounties, partly, as has been seen above, granted by the government, partly derived from industrial funds.

The final situation, though different in its effects upon those enjoying fixed incomes and upon the sheltered industries, was probably not in its short-run results so widely divergent, as has sometimes been suggested, from the alternative consequences of deflation and wage adjustment. The latter might, however, over a longer period have permitted an even greater expansion of gold mining than has taken place, an expansion which has been estimated by Mr. Gemmill, of the Transvaal Chamber of Mines, as being capable of yielding employment to a further 129,000 natives and 14,600 Europeans, as the result of a 10 per cent. fall in costs. It is, however, by no means certain that the whole of the increased cost of living due to the imposition of tariffs has been reflected in higher wages either of natives or of Europeans, or that the removal of protection would result in any equivalent reduction of wages and costs in the mines. A considerable rise in real wages of European mine-workers since 1925 has been mainly a consequence of the continuance of a relatively constant level of money wages in a period of falling prices. It is impossible to judge whether a further 10 per cent. rise in real wages would have enabled the mines to enforce wage reductions which they had hesitated to enforce when real wages rose 23 per cent. between 1925 and 1933. But there can remain little doubt that when all reasonable allowance has been made for the effects of increased costs upon mining and existing export industries and for any consequent maldistribution of resources, the protective policy has made quite a substantial addition both to employment and to the national income. That addition might, it is true, have been at least equally well secured by the alternative policy of deflation and wage reduction, but it could only have been thus secured in the face of very considerable opposition.

But though protection may have served somewhat to mitigate

the intensity of European unemployment or mis-employment and to diminish the competition with native workers, it has by no means removed the problem completely. The difficulties of individual Europeans in competition with African unskilled workers remain very real, and their alleviation one of the most acute practical problems of the Union. Broadly, two methods of dealing with the problems are available. The first is that of maintaining high European levels of earnings by colour-bar restrictions on the advancement of native workers. This method has, however, its limits. In South Africa profits, skilled wages, and unskilled wages share the total product in such proportions that skilled wages are approximately three times the average value of output per person employed. In England it is so divided that skilled wages are approximately equal to the average value of output per person. Since the share of profits is not markedly different in the two countries, the gain of skilled labour is largely at the expense of unskilled labour, that is, at the expense partly of native workers, partly of unskilled Europeans. The more the field of employment of natives is restricted, the more is the high level of skilled wages derived from the exploitation of the poorer Europeans. Ultimately the high-wage policy must conflict with the civilized labour policy and choice must be made between them. On the other hand, the greater the ratio of native labour to white labour, the better is the prospect that industry will be able to pay existing wages to European skilled labour, or wages not substantially less.

The alternative to the method of restriction is the method of expansion. It was suggested above¹ that the European's contributions to economic activity, whether in the Union or in other parts of Africa, may be divided under four main heads. He provides, first, the knowledge of technique; second, organization and discipline; third, capital; and fourth, skilled operation. With the exception of a few Indian and coloured owners of small factories, both the provision of capital and the organization of industry have remained almost exclusively in European hands. In any new and growing industry both the technical control and the operation of the more skilled processes require, as a rule, European assistance. But as an industry becomes established and the processes are

¹ See above, p. 1359.

reduced to a routine which, even if imperfectly comprehended, may be reproduced by rule of thumb, the need for European supervision is gradually reduced. In the Belgian Congo or West Africa native operatives have shown themselves competent in such circumstances to take over many semi-skilled tasks. Where that possibility exists some restriction on native advancement becomes necessary, if it is desired that the European shall retain his post at a rate of wages more than proportionate to his greater skill.

The only effective method of avoiding this necessity is by the opening up of new sources of demand for labour. It is in an advancing and expanding phase of industrial activity that the demand for such qualities as distinguish Europeans is greatest. If through the application of restrictions the advance is brought to a halt, native competition will almost certainly grow progressively keener, and restrictions will become at the same time more necessary and more difficult to enforce. If economic development can be pushed on more rapidly, not only will the demand for European labour be increased, but also that for native labour, and the field of competition will be narrowed. A policy of industrial expansion may, perhaps, require that the proportion of the whole income going to Europeans be reduced, but the total divisible income is likely to be so increased that their absolute share will be greater.

A policy of expansion requires in the first place adequate supplies of capital that will be invested in the expectation of a return which it is within the capacity of industry to pay. While actual shortage of capital has not been a serious handicap to South African development, the rate of return demanded has sometimes been beyond the probable capacity to pay of small and unestablished industries, chiefly, it would appear, because prospective yields in mining have set up standards of expectation with which more stable industries can hardly compete. It requires, secondly, a prospect that during at least an initial period wages shall not be fixed at a level beyond the ability to pay. In this connexion attention may be drawn to the recommendation of the Customs Tariff Commission¹ 'that it is urgently necessary to co-ordinate not only the activities of the Board of Trade and Industries and the Wage Board, but also those of the various other controlling bodies which

¹ *Report*, op. cit., U.G. 5, 1936, para. 349.

operate under the present system of State regulations of the country's economic life'. It requires, thirdly, that there should exist European labour possessing those qualities of knowledge and initiative that are needed for the expanding industries.

The Carnegie Commission has emphasized the importance of education as a means of improving the position of the poor white.¹ As native education and experience improve, competition must become more intense for Europeans who have no special industrial qualifications. It can be most effectively mitigated by the education of those qualities of responsibility and initiative which are as yet comparatively undeveloped in the native. The Carnegie Commission has emphasized also the damaging effects of restrictive policies upon the outlook of those that they are designed to assist.² 'It is insufficient', they wrote, 'if the State merely provides the European with employment without at the same time taking measures to ensure that those who are assisted in this way are spurred on to greater personal efforts and to improving their efficiency. . . . A policy of protection by reservation of work to the European should be treated as merely a measure of transition for a period during which the poor white is given the opportunity to adapt himself to new conditions in South Africa. It will be disastrous for the poor white himself if any protection given him is of such a nature that it results finally in impairing his ability to compete with the non-European on the labour market. With a view to the welfare of the poor white, the period of protection should be made one during which they are trained to greater efficiency than they often have now.'

There is another aspect of native competition which requires brief consideration. The fear of such competition is twofold. It arises partly from a desire that no European shall sink to the native level of living conditions, and partly from the fact that the present native level is one at which no European can maintain what is regarded as a decent existence. The former ground of fear can be removed only by making Europeans able to earn more than the natives. The latter can be removed not only by giving the European a differential advantage, but also by so raising the native

¹ Joint Findings and Recommendations, *Report of the Carnegie Commission*, op. cit., 1932, paras. 14-19, 31-7.

² Ibid., paras. 68-9.

standard of life that it will no longer be a level at which decent existence cannot be maintained. The higher are native standards of life in the urban areas, the less depressing will native competition be upon the poor white community. Moreover, the native is not only a competitor. He is also a consumer. If his earning capacity is raised, so will be his spending capacity. The progressive development of this great potential market must provide many outlets for profitable European employment. The competitive relationship between European and native workers has in the past been stressed, perhaps over-stressed. For some individual Europeans it will always be the predominant consideration. But in many respects European and native labour is, and will remain, collaborative. A greater emphasis on this aspect, and a greater development of industries depending upon such collaboration, appears to be in the interest both of individuals of the two races and of the community as a whole.

Since 1925 the policy of the development of secondary industries has almost certainly accelerated the rate of growth of the modern economic system. But the ratio of natives to European workers has not, as was seen above,¹ been materially altered. It may reasonably be expected that this policy will be maintained, and that the absorption of natives into the modern system will proceed in the future somewhat faster than the rate of population growth. Whereas in 1932 liquidations and reductions of capital had exceeded the investments in new companies and the addition to the capital of older companies, in 1933 the latter amounted to £15,000,000, in 1934 to as much as £36,000,000, and in 1935 to about £21,000,000. But even so rapid an expansion as this cannot be expected to eliminate immediately the fear of European unemployment and of native competition. The apparent need for restrictions on the field of native employment must continue, and there must always be individuals to whom it is a benefit.

Nor must it be thought that such restrictions are unique. In almost every country there is a pressure exerted either by trade unions or by public opinion upon the freedom of the employer to buy labour freely in the cheapest market. The problems presented by native competition have much in common, as has often been

¹ See above, p. 1363.

pointed out, with those presented in Great Britain by the inroads into the labour market, since the War, of female labour. In each case the long-run advantage lies in the direction of utilizing the new supplies of labour to increase the total production of the country. But in each case such adjustment must require a painful transition, with great hardship to individuals who have acquired skill which can no longer command what is regarded as an adequate wage. Almost every community does in fact attempt to achieve a compromise between the most rapid possible economic progress, to be gained by complete freedom to purchase labour in the cheapest market, and a measure of security and stability during the necessary period of transition, to be obtained by the countenancing of certain restrictions on that freedom. But there is always a danger, in South Africa as elsewhere, that the gain of the comparatively few from security may be allowed to predominate over the interest which the majority have in progress, so that for a controlled transition there may be substituted an increasingly artificial stagnation.

(b) *Southern Rhodesia*

The economic development of Southern Rhodesia is relatively recent. Some reference has already been made to various phases in the history of the Chartered Company;¹ in effect, it may be said that the fate of the Company's rule was determined when the early hopes of discovering gold on a large scale proved to be without foundation. The receipts of the Company from royalties and the like were inadequate to bear the growing cost of administration, and the progress of the territory was further affected by the Matabele rebellion of 1896 and the rinderpest outbreak of the same year. But there were many respects in which Southern Rhodesia profited from the existence of the Company. The latter was able to provide railway communications, and to undertake extensive experiments in stock-breeding and the like which, if they had been carried out by state agency, would have left the territory with a burden of fixed interest on its loan capital. Like the Union, Southern Rhodesia has a European population which looks on the country as its permanent home. The climate does not, as it

¹ See Chap. VI, p. 157; Chap. IX, pp. 376-7; Chap. XII, pp. 732-3.

does farther north, necessitate periods of recuperation in a more healthy environment. The high veld plateau, where European farming is mainly concentrated, is in ordinary years well watered, and free from many of the difficulties which confront farmers in the Union. But the territory has suffered difficulties of its own, many of them consequent upon the great distances which separate it from its markets, and upon the lack of any sufficient volume of local consumption to provide a ready outlet for other than the staple agricultural products in which international trade is possible.

Southern Rhodesia differs markedly from the Union, however, in regard to the relative proportions of its European and native population. Whereas in the Union there are approximately 3·3 natives to 1 European, the ratio in Southern Rhodesia is approximately 21·1 to 1. This greater disparity of numbers, and the more recent development of the territory, have meant that a far smaller proportion of all natives are engaged in work for European undertakings, or upon farms or in domestic service. Approximately 37 per cent. of the adult male natives of Southern Rhodesia are employed in the modern European economy as compared with 67 per cent. in the Union.¹ They are reinforced by large numbers of 'foreign' natives from Nyasaland, Northern Rhodesia, and Portuguese East Africa. Of the total number of 221,410 natives engaged in work for European undertakings in 1936, as many as 133,758 came from outside.²

Of the European population, which amounted in 1936 to 55,422, as many as 43 per cent. were resident in the two largest European centres, Salisbury and Bulawayo. Of the adult male Europeans in the territory, 22·3 per cent. were occupied in 1931 in agriculture, 10·0 per cent. in mining, 14·6 per cent. in transport, and 33·3 per cent. in other industrial and commercial pursuits. Mining, though the number of Europeans employed is not large, is from the aspect of the economy of Southern Rhodesia predominantly important. Of the value of exports of Southern Rhodesian produce, which in 1936 amounted, including the gold premium, to approximately £9,268,000, the gold export accounted for 61 per cent. of the whole. Other exports of metals and minerals, of which

¹ See Chap. XI, p. 690.

² *Ibid.*, p. 701.

chrome, asbestos, and coal are the most important,¹ raised this total to almost 80 per cent. of all exports. Of the agricultural exports of the territory the most important by far is that of tobacco. In 1936 the total value of tobacco exports was £710,863, of which unmanufactured leaf accounted for 87 per cent. The export of meat, almost exclusively destined for the British market, amounted in 1936 to approximately £158,000. This figure has grown greatly in recent years—it never exceeded £20,000 before 1933—but it is still no more than 1·7 per cent. of all exports. Citrus exports, also consigned chiefly to Great Britain, have declined substantially both in quantity and value during recent years, and amounted in 1936 only to some £22,000. The exports of maize were valued at £313,000 in 1936. But for that year the total agricultural exports did not exceed 9·8 per cent. of the exports of the territory, if gold is valued inclusive of the gold premium.

The mining of gold in Southern Rhodesia, in marked contrast to the Union, is largely in the hands of small workers, and, as explained more fully elsewhere, the development by small producers has been the basis of the policy of government.² While the activity of mining is important as the main source of the territory's exports, as contributing a substantial part of the revenues of the government, and as providing the most profitable market for the produce of agriculture and the secondary industries, it is not a large direct employer of European labour.³ The numbers employed in mining of all kinds rose, it is true, from 1,432 in 1931 to 3,094 in 1936. But even so they do not considerably exceed the numbers employed in transport, in commerce, or in public administration. The capacity of the territory to pay wages, salaries, and dividends depends, however, largely on the volume of primary production in mining and agriculture, and on the possibility of discovering profitable markets for these products.

As in the case of the Union, the levels of wages in sheltered industries, and more particularly in commerce and in transport, have been high. Their level had been dictated originally by the need to attract skilled or semi-skilled European workers to the territory,

¹ See Chap. XXII, pp. 1494–5.

² *Ibid.*, p. 1493. See also S. H. Frankel, *op. cit.*, chap. v, p. 238.

³ See Chap. XI, p. 690.

and even after the immediate need for an excess above similar rates elsewhere had disappeared, the relatively strong bargaining powers of the workers in these sheltered industries would appear to have succeeded in diverting to them a somewhat excessive share of the total income of the territory. The primary producers could for a time at least be exploited, paying more for consumable goods or receiving a smaller share of the final value of their products. This remained possible so long as existing farmers or industrialists remained solvent and prepared to accept what was left to them rather than go out of business. But there were signs during recent years, confirmed by the evidence of the Committee of Enquiry into the Economic Position of the Agricultural Industry of Southern Rhodesia of 1934, that the financial position of many of the farmers was becoming increasingly precarious. They have been assisted by a variety of measures. The poorer among them are rarely liable to income tax.¹ A Maize Control Board, established in 1931, and since somewhat modified in detail, has maintained differential prices in the home market on the one hand and in the export market and the market for feed for exportable cattle on the other. The Cattle Levy and Beef Export Bounty Act² imposed a levy on cattle slaughtered for local consumption and provided a bounty, to which the government makes a contribution, on exports of chilled, frozen, and boned beef, and on meat extracts. A Tobacco Marketing Act³ has limited by quota sales to the 'protected' markets, those of the United Kingdom, the Union, and for local manufacture, and has sought to stimulate sales in new markets. A marketing scheme for dairy produce provides for a levy upon all sales of butter and cheese, from which a bounty is paid upon exports. In addition steps have been taken to ease the financial pressure upon farmers embarrassed by debt.⁴ The purchase price of farms granted to Empire settlers was reduced by two-thirds, and interest charges abolished. Interest charges on Crown lands held under various agreements, and upon debts for fencing, wells, and similar purposes, were reduced or in some cases abolished. A moratorium was granted upon debts to the government for lands purchased or leased. Quitrents and certain administrative

¹ See Chap. X, p. 549.

² No. 21 of 1933.

³ No. 5 of 1936.

⁴ See Chap. XII, p. 820.

charges were abolished. Finally the Farmers' Debt Adjustment Act provided additional funds for the alleviation of farmers' debts.

During the years 1936-7 there has been a very considerable recovery of agricultural prices and of the volume of agricultural exports. The quantity of maize in 1936 was treble that produced in the previous year. The export of meat, which had already increased in 1935, was in 1936 approximately 50 per cent. greater both in quantity and value than in 1934. The export of tobacco, while below the 1934 figure, was very substantially higher than during the depression years. Despite the recent difficulties of the farming population, the number of Europeans actively engaged in farming has not very markedly declined, though it had ceased to grow during the period of depression.¹ Farm owners, who numbered 2,606 in 1931, were still as many as 2,523 in 1935.

It is inevitable that agricultural and mineral prices should fluctuate more widely than the costs of sheltered services. Too much emphasis must not be placed upon what may prove to have been temporary depressions in these primary industries. It is sufficient that those engaged in them should receive over a period of years a scale of rewards high enough to induce a fresh generation of producers to devote their lives and their resources to these occupations. But if competition from other countries both in agriculture and mining remains as strong as it is to-day, with the inevitable repercussions upon the divisible income of Southern Rhodesia, it is difficult to resist the conclusion that some re-division of the proceeds of production will sooner or later be the alternative to a decline in the level of European settlement and output. As in the Union, the whole system of rewards for skilled and semi-skilled European work may require to be progressively adapted to the still largely unknown productive capacity of the territory, so that they may reflect rather the richness or poverty of the country than, as they have in the past, its attractiveness relatively to other places as a place of new settlement.

By the various measures described above, the cost of implementing the policy 'that a white agricultural population must be the basis on which to build a white colony', advocated by the Committee of Enquiry of 1934, has been shared by the whole European

¹ *Annual Report of the Department of Agriculture and Lands, 1937*, pp. 4-5.

community, and to some extent also by the native community. The same results could, as in the Union, possibly have been achieved more laboriously, but in the end with less administrative complication and with less possibility of errors of judgment, by a necessarily painful process of deflation, whereby the bankruptcy of farmers and of other exporters would progressively have enforced reductions of incomes and of wage and salary scales throughout the territory. Whether the resulting set-back to the general development of the colony would have been fully counter-balanced by the ultimately effective readjustments, it is not easy to judge.

Various circumstances, including the wide margin of undistributed land and the opportunities open to small-scale mining, have prevented the emergence of a poor white problem similar to that of the Union. At the time of the 1931 census there were 1,234 European males returned as unemployed. The growth of this figure, which was some two and a half times as great as in 1926, caused at the time some concern. But it did not exceed 6.6 per cent. of the occupied male populations, and as compared with the incidence of unemployment in other countries, that of Southern Rhodesia has not been excessive. Its existence has, however, somewhat reinforced a natural tendency to reproduce the colour-bar restrictions of the Union.

While there is no actual colour-bar legislation, the Industrial Conciliation Act¹ and the strength of organized labour in transport and the more skilled occupations have been able to make difficult the rise of any large class of native skilled workers, occupied in the European economic system. It has been recognized, however, as for instance by the Railway Court of Enquiry, 1929, that 'in the circumstances of this colony the effect of pushing up wages on other than economic grounds would be to lessen the number of white men who could be employed at the higher rates and to bring those displaced, or who could not or would not be employed, because the minimum rates fixed were considered unduly high in relation to the economic value of the work to be performed, into closer competition with the native'.

While in practice there has been a slow but steady growth of a

¹ See Chap. XI, p. 691.

unified economic system, with the native filling the lower grades of labour,¹ there has been little desire to make the progress of such unification so rapid as to cause excessive dislocation and suffering to those Europeans who have acquired skill or have invested resources in trades which in a completely unified system might become the proper sphere of native producers. Rather, it may be said that it has been the aim to make the native economic system sufficiently vital and productive, and to make available sufficient lands for native occupation, so that the pressure to over-hasty unification may be reduced.

(c) *Nyasaland*

The economic development of the territories north of the Zambesi is even more recent than that of Southern Rhodesia. European penetration may be said to have begun with the arrival of the missions; the Livingstonia Mission in 1874 and the African Lakes Corporation in 1878 led the way. But the conflict with Arab slave traders and others resulted in continuous fighting for some years, and effective European occupation came slowly. By the time that the country was pacified some measure of economic progress had already been achieved. The European population, which had been no more than 57 in the whole of British Central Africa and Northern Rhodesia in 1891, had increased so that in 1896 there were 300 Europeans in Nyasaland alone. By the latter year an Indian population almost equal to the European had already grown up. The progress of the territory has been largely dependent on the development of the transport system, of which a detailed account has been given elsewhere; direct communication with the sea was finally completed in 1935.² The European population has grown slowly; in 1936 it was estimated to be no more than 1,838, of whom the great majority live in the Shire Highlands around Blantyre. Some 1,303,219 acres, or about 5 per cent. of the total area of Nyasaland, are alienated to Europeans, mostly in large holdings in the hands of companies and the like.³

¹ H. Clay, *Report on Industrial Relations in Southern Rhodesia, 1930*. C.S.R. 3, 1930, pp. 42, 43. The number of urbanized natives working at specialized crafts has shown a steady increase, but by 1936 was no more than 3,043.

² See Chap. XXIII, p. 1577.

³ See Chap. XII, p. 756.

Nyasaland differs from most of the East African territories in the great importance of her agricultural exports. This may be in part a regrettable consequence of the lack, at present at least, of any mineral development similar to that of Kenya or Tanganyika, let alone to that of Northern or Southern Rhodesia. But it is in part at least a welcome consequence of a policy which has encouraged the natives to grow whatever crops they are able to, and has provided facilities for their marketing and transport. Almost the whole of the £796,627 of exports of local produce in 1936 was derived from agricultural products. But this dependence upon agriculture has had certain undesirable repercussions. The demand for labour in the territory is more limited than in those possessing minerals capable of profitable exploitation, and the proportion of natives seeking work abroad, which has always been higher than in other British territories, has created a problem of grave concern to the administration.¹

As in other territories the difficulties of European settlers have required the assistance of the government during the years of depression. Growers of tea have benefited by the international tea restriction scheme.² Those of tobacco have been helped by the creation in 1936 of a marketing scheme with a pool for the disposal of surplus leaf, and by advances to enable them to plant their current crops despite the embarrassment caused by the lock-up of their working capital in heavy unsold stocks. Despite these recent difficulties the economic development of the protectorate would appear to be on stable if on narrow lines; its great need is the expansion of its cultivation, more especially in the northern areas, which are still largely undeveloped.³

(d) *Northern Rhodesia*

The economic history of Northern Rhodesia began somewhat later than that of Nyasaland, and when the two administrative areas, into which the territory was originally divided, were amalgamated in 1911, economic development had not proceeded far. Before the great period of expansion that began with the exploita-

¹ See Chap. XI, pp. 701 and 707.

² See Chap. XIII, p. 924.

³ Governor's speech, *Summary of the Proceedings of the Legislative Council of Nyasaland*, 1935, para. 39.

tion of the copperbelt¹ in 1929, the European settlement of the territory had been meagre. The British South Africa Company made a beginning of settlement when the railway reached Broken Hill in 1906, but at the end of 1930 there were no more than 260 farms occupied. The area of settlement has been mainly within a strip of some thirty miles on each side of the railway. There are two outlying settlement areas at Abercorn and Fort Jameson, and individual holdings in more remote places. The census of 1931 gave 544 male Europeans as engaged in agriculture.

The markets for agricultural produce, apart from the tobacco grown chiefly in the Fort Jameson area and the small amount of coffee near Abercorn, are almost exclusively local. There was at one time a substantial trade in cattle with the Katanga mining area, but local sources of supply have now been developed and that source of demand has almost disappeared. The costs of transport and the abundant competing supplies in Southern Rhodesia make any southward outlet to cattle markets entirely unremunerative. Maize is grown in excess of local needs in a good year, and an attempt has been made since 1936 to make its cultivation more profitable to farmers by means of a control board operating upon a system somewhat similar to that of Southern Rhodesia. Of a production of about 440,000 bags in 1936, including about 160,000 produced by natives, local consumption absorbed about 210,000 bags. Of the remainder approximately 131,000 were exported overseas, 58,000 under an agreement with the Southern Rhodesian Maize Control Board were exported to that colony, and 45,000 were sent to the Union. In a year of big crops and a rising world demand for maize its operations were very satisfactory to both European and native producers. It remains to be seen whether in a more normal year it can make substantial additions to the income of the farming community. Wheat is grown only with the assistance of irrigation in the neighbourhood of Lusaka. Until lately almost half the amount necessary for consumption has been imported, but since 1934 there has been a considerable increase of the acreage planted, and only a low yield in 1936, due to rust, prevented a close approach to self-sufficiency.

Though the growth of demand has done something to mitigate

¹ See Chap. XXII, p. 1495.

the earlier difficulties of settlers, more particularly along the railway strip, and though the acreage under cultivation has increased by about 20 per cent. during the years since the recent mining development began, it would appear that any extension of settlement must depend mainly upon the comparatively slow growth of local markets, and may be increasingly affected by the competition of native producers in the supply of foodstuffs suitable for native consumption.

The only other product of European enterprise, apart from minerals, which has been exported on any considerable scale, is the timber cut for railway sleepers and other purposes on the banks of the Zambesi, of which the exports in recent years have been normally of the value of about £60,000, but which amounted in 1936 to nearly £143,000. An increasing shortage of timber supplies is, however, likely to lead to a considerable reduction of output within the next decade.

Since the development of the copperbelt the prosperity of Northern Rhodesia has become largely dependent upon that metal. The total recorded exports of local produce in 1936 amounted to £5,936,692. Of this, £4,994,712 was the value of the copper exported, and a further £635,210 represented the value of the cobalt, zinc, vanadium, and gold, so that in all the export of metals amounted to 94·8 per cent. of the whole. The values recorded for customs purposes are, it is true, the market values overseas, and in consequence somewhat overstate the value of the export to the territory, but the broad conclusion remains unaffected. The mines gave direct employment in 1936 to an average of 1,847 Europeans and 16,333 natives. The number is now far lower than at the peak of construction in 1930, when nearly 32,000 natives found employment, but is well above the low level of 1932 when native employment was a little over 8,000. The export of copper, which began in 1930, has steadily risen, and reached in 1936 a figure of 141,000 tons.

Despite the low proportion of Europeans to natives in the territory as a whole—it was 1 to 94 in 1931, and has probably fallen back to approximately 1 to 140 since the completion of the construction period in the copper mines—the proportion of natives working in European employment is greater than in Southern Rhodesia. It

was estimated in 1935 that 66,702 natives were employed within the territory, and 49,030 outside it. The total of 115,732, excluding those occupied in tax-relief labour, would be approximately 40 per cent. of the taxable male population of 288,000.

(e) *Tanganyika*

In Tanganyika economic development was far more delayed than in the surrounding territories. The German settlement first began in the years following the foundation of the *Deutsche Ostafrikanische Gesellschaft* in 1885, but the country could not be said to have been pacified until after the suppression of the Maji Maji rising in 1906. The Tanga railway did not reach the fertile foothills of Kilimanjaro till 1911, but by 1913 there were nearly 900 European planters, mostly along the railway line from Tanga to Moshi.

The German estates were sold by auction during the period 1920-4, and passed into a variety of hands, mainly British, but also Indian, Greek, Syrian, and other. The embargo on the holding of land by Germans was removed in 1925, and large numbers of the original estate owners have now returned. In 1929 there were in all 1,985 holdings of which 508 were British, 347 German, 337 Indian, and 240 Greek. Of a European population estimated at 8,455 in 1935, as many as 2,665 were German, and during that year a further 197 immigrated.

It must be realized that there are certain physical obstacles to the rapid development of the territory. A considerable part of it is subject to tsetse fly¹ and large areas are uninhabited on account of the lack of water.² The area alienated to Europeans amounts to 2,700,000 acres or 1½ per cent. of the whole. As regards its exports Tanganyika falls midway between the highly mineralized territories such as Northern Rhodesia, and Nyasaland with its almost exclusive dependence on agriculture. Of a total export in 1936 of £4,516,284 of local produce, £489,796 represented the export of gold bullion. The Lupa gold-field has attracted a large digger population estimated at 900 Europeans and about 17,000 natives.³ Other deposits near the shores of Lake

¹ See Chap. XVII, p. 1090.

² See Chap. XV, p. 1044.

³ See Chap. XXII, p. 1497.

Victoria and elsewhere have made some contribution to the total. Of the agricultural exports by far the most important is that of sisal, which reached a value of £1,873,312 in 1936. Exports of cotton, groundnuts, and hides are also substantial, amounting to nearly £1,500,000 in the same year. Many of the estates and of the individual settlers are reported to have experienced considerable financial difficulties in recent years, in particular owing to the collapse in the price of sisal during the depression, when it fell from an average for the previous eight years of over £40 to as low as £12 10s. in 1931, recovering gradually to about £28 in 1936. The volume of sisal exported has, however, grown from under 46,000 tons in 1929 to over 82,000 tons in 1935.

Tea and sisal are both estate crops rather than profitable opportunities for individual settlers without considerable resources; one of the difficulties of the territory has lain in the wide variation in the price of sisal in recent years. Those who have attempted mixed farming, more particularly in the south-western plateau around Iringa, where they are from 200 to 400 miles from the railway, would appear to have found it difficult to do more than make ends meet upon a very modest scale of living. Of the German settlers many are said to be heavily mortgaged and indebted to the Usagara Trading Company, financed by the *Übersee Gesellschaft* of Berlin. European wages for farm managers and assistants are very meagre, and, unless improvements of transport make possible the introduction of new export crops, the prospects of any considerable development of European farming must be regarded as remote.

(f) *Kenya and Uganda*

The development of Kenya and Uganda followed very shortly after that of Nyasaland. As is shown in the account of European land settlement in Kenya given in a previous chapter, its origin is closely connected with the construction of the Kenya-Uganda railway.¹ By 1903 there were about 100 settlers in the vicinity of Nairobi, but economic progress was slow and relative prosperity only began in 1909. The European population numbered approximately 18,269 in 1936, and 1,807 European farmers occupied 4,580,000 acres. Some details regarding the present position of

¹ See Chap. XII, p. 820, and Chap. XXIII, p. 1582.

European farming have been given in the chapter above referred to, with a reference to the steps which the administration has been forced to take in order to assist the farming community. It is difficult to distinguish the temporary effects of depression from other causes, such as the inflated prices paid for land, the fact that a large number of settlers have no experience of farming and some of them are not well adapted for colonial life, or that there have been periodic attacks of locusts and other crop pests; whether the cause be permanent or temporary, assistance has been given by a series of measures similar in their main characteristics to those employed in the Union and Southern Rhodesia. Apart from assistance by credit facilities and the like, to which reference has already been made, duties of from 10 per cent. to 64 per cent. above the normal rate have been imposed on articles such as wheat and wheat flour, butter, and sugar, which compete with local products; the railway rates have been differentiated, export rates being, for example, one-third of the rates on imported flour, and wheat further helped through the Sale of Wheat Ordinance of 1930. Butter has been the subject of a levy and export bounty, and maize has received a subsidy. It is obvious that Kenya is peculiarly vulnerable in respect of the effect of world prices on its limited number of exportable agricultural products, since there has been a relatively higher expenditure of both public and private capital on its development than in any other African colony,¹ thus creating an obligation which is doubly onerous in times of depression.

Mining until recently showed little advance, and is even to-day of small importance in Kenya as compared, for example, even with Tanganyika, though the production of gold has increased considerably.² But even in 1936 the export of gold was only equal to about 7 per cent. of current exports of local produce. Of this, coffee is by far the most important, accounting for some 25 per cent.; sisal comes next with 18 per cent. Tea, and until recent years maize and sodium carbonate, have all exceeded the gold in value. Thus, like Nyasaland, Kenya has remained predominantly an agricultural country, without many of the opportunities of

¹ See Chap. XIX, p. 1350, and Chap. XXIII, p. 1583.

² See Chap. XXII, p. 1498.

supporting the high standard of living of the European population out of the profits of mining that are enjoyed by the Union and to a less degree by the Rhodesias and by the Belgian Congo.

In Uganda there has been no parallel history of settlement. The European population was estimated in 1936 at 2,000, which was approximately its level in 1931. But of this population only an insignificant minority would regard the territory as their permanent home. In 1931 some 76 per cent. of the European community were either officials or missionaries or their families. Of the remainder, 282, including 57 occupied in clerical tasks, were engaged in industry and commerce, and only 103 in agriculture. The recent increase of numbers concerned in mining or prospecting is probably drawn from this class rather than from new immigrants.¹ The economy of the protectorate now centres largely on cotton,² almost entirely a native crop; it forms 80 per cent. of the total export. Minerals, in the form of tin and gold, form only about 3 per cent.

(g) *Southern and Eastern Africa as a Group*

It may be said that the group of East and South African territories, comprising the Union and South-West Africa, the High Commission Territories, Southern and Northern Rhodesia, Nyasaland, Tanganyika Territory, Kenya, and Portuguese East Africa, form one economic unit. The territorial boundaries by no means represent effective limits to the movements of labour. The transport systems, by rail, by road, and by air, are closely interlocked, and though certain restrictions on trade exist, in many cases ostensibly for the prevention of the spread of animal diseases, over large parts of the area, customs agreements or the Congo Basin Treaties prevent the growth of any considerable obstacles to inter-territorial trade. Until a few years ago the Belgian Congo would certainly have required to be included in this area of common development, but in more recent years a policy aiming at the 'stabilization' of labour³ has diminished considerably its dependence upon labour from Northern Rhodesia and Nyasaland, and the development of local sources of supply of foodstuffs has made

¹ H. B. Thomas and R. Scott, *Uganda*, 1935, pp. 359-60.

² See Chap. XIII, p. 904.

³ See Chap. XI, p. 681.

it almost independent of its neighbours. On the other hand, until the recent reversal of the policy of not recruiting for the Transvaal from north of the 22nd parallel of latitude, the southern part of the continent was at least partially isolated from the northern. Even now the money wages payable in the more northerly territories are substantially lower than those in the Union, but the volume of native migration is insufficient to bring them into closer equality.

Within this group of territories there were living in 1936 approximately 2,145,000 Europeans, 327,000 Asiatics, mainly Indians, and about 28,000,000 natives. It is not easy to say what proportion of this native population are adult males capable of work. The number is probably of the order of 6,500,000. Of these, there were in European employment of all kinds—government, railways, mines, agriculture, industry, commerce, and domestic service—about 2,230,000 in 1936: that is about 34 per cent. of the total. These figures are largely estimates subject to a considerable margin of possible error, but there can be little doubt that, even if in detail they cannot be trusted, the broad picture that they convey is sufficiently trustworthy for our purpose.

But they need some modification before they can serve as an index of the progress of a unified economic system. They exclude the very large numbers of natives who, through cultivation of such crops as cotton, tobacco, groundnuts, grain or cattle for sale, have in part at least attached themselves to the European economy, and the quite substantial numbers of natives whom they may employ, either permanently or, as in the case of cotton, seasonally. Thus the 1931 census of Nyasaland points out that some 32,000 were then growing cotton for sale, and some 48,000 were registered tobacco growers, many of these employing assistants. There were a further 10,000 occupied in the fishing trade, and smaller numbers as market-gardeners, milkmen, butchers, cobblers, smiths, carpenters, tailors, and laundrymen. In Uganda there are large numbers of natives dependent in part at least upon the growing of cotton and coffee for export markets. It is not easy to estimate the number of such growers with accuracy, but from evidence of total acreage planted and of size of holdings the total number must be in the neighbourhood of 750,000. In Tanganyika Territory there are also large numbers near Lake Victoria growing cotton

and employing other natives in large numbers in the cotton-picking season.

The material does not exist from which any satisfactory calculation of the total of persons working in the newer economic system could be made for the whole of this area. Nor is it possible to define with any precision those who do and do not take part in it. It is a consideration of especial importance that in Africa the woman is usually at least as important a producer as the man, and unless one knows whether the women-folk are continuing to cultivate gardens in the reserves while their men are away at work, or on the other hand have accompanied them to work, one can form no trustworthy picture of the effective extent of the native absorption into European economy.¹

Clearly during the last fifteen years it has progressed very considerably, and equally clearly, with the steady increase in Central Africa of the scope of native cash-crops, the effective labour supply, on which further European settlement or further mining development must depend, will prove the important limiting factor. There are already appearing signs of scarcity of labour, as for instance in the cotton-growing areas in Tanganyika, where labour for the ginneries was for a time almost unobtainable. It would seem likely that increasing demands and the increasing opportunities for making an income by cultivation must progressively result in higher wage scales. It is, however, clear that a subsistence economy still predominates over the greater part of Africa, and the modification of this to make more easily possible the payment of tax and the purchase of imports is still the greatest single problem of most of these East African territories.

It will be seen from this review of the recent history of the territories of South and East Africa that, with the exception of Uganda and Tanganyika, and to some extent Nyasaland, governments have been led by force of circumstances during the last few years to give growing support to European agriculture. It would be easy to deduce from this the inference that agricultural settlement is an unnatural growth that can survive only with artificial aids. Any such simple conclusion would almost certainly be misleading. It must be remembered that South and East

¹ See Chap. XIII, p. 978.

Africa have shared, perhaps in greater measure because distance from centres of consumption has particularly affected them, in an agricultural depression that has been world-wide, and in a progressive narrowing of markets due to the increasing demands for national self-sufficiency in many of the importing countries. Almost every country whose economy is built upon agricultural exports has been driven during that depression either to attempt to maintain profits by currency depreciation, as in Australia, the United States, the Argentine, and Brazil, or to create differential prices at home and in the export markets by some such devices as have been the main resort of African territories. Moreover crop-yields, more particularly in Kenya, do not compare unfavourably with those of other similar exporting areas. But the accumulating weight of evidence would seem to inspire doubts as to whether European agriculture will do more, even in good times, than make possible a very modest living as a return for hard work and the incurring of grave risks of loss of invested capital, and whether in bad times it must not prove a recurrent charge upon the revenues of the governments. Even in more normal times the support given to farming constitutes a burden directly or indirectly upon the incomes of those concerned in mining or other enterprises.

The more fundamental question is whether the most valuable contribution that European capital, enterprise, and knowledge can make to African development lies in the maintenance of a European farming community. Native agriculture, though many of its practices are based upon a valuable empirical wisdom, has undoubtedly much to learn; that is especially true of African methods of animal husbandry. But under the guidance of Agricultural Officers, backed by both long-range and local research, it is learning fast, and in many parts of Africa the price levels which in recent years have necessitated help to European agriculture, have proved sufficient to stimulate increases of native production. There are other fields, in particular those of marketing, transporting, and financing the movement of native produce, in which European assistance is both more necessary, and can on that account secure a greater premium. In some areas at all events it must, as the Committee on the Economic Position of the Agricultural Industry in Southern Rhodesia recognized, become an increasingly difficult

problem to judge how far the ideals of a particular colony are necessarily bound up with the existence of European farming, and how much other sections of the community should be prepared to contribute to its maintenance.

(h) *West Africa and the Congo*

While European settlement has been the basis of the economic development of those territories which have thus far been considered, the development of the territories of both British and French West Africa, of French Equatorial Africa, and in the main that of the Belgian Congo and Angola has taken other forms.¹ In the British territories, European capital has, apart from mining enterprises, been mainly engaged in the provision of transport and marketing facilities.

On the Niger Coast, Portuguese, British, and other European merchants established trading stations as early as the seventeenth century. But they were little concerned with political adventures, and interested almost exclusively in the trade in slaves. It was only after the progressive abolition of this trade in the early years of the nineteenth century that there was any substantial advance in the commerce in other commodities, but during the following decades a substantial export of palm oil was gradually built up.

It was not until 1861 that Lagos was occupied, mainly to prevent its continued use as a slave market. Until 1886 it was administered first by the Governor of Sierra Leone, later as part of the Gold Coast Colony. Before the period of the scramble for Africa the British merchants were unorganized, and usually engaged in keen mutual competition. In the face of opposition from newly established French companies with numerous trading stations, the British merchants came together in 1879 under the leadership of Sir George Goldie, in the United African Company, enlarged three years later into the National African Company. By 1884 the French competitors had been bought out, and the British predominance secured the recognition at Berlin of the British influence, and the establishment in the following year of a protec-

¹ The European population of Nigeria is 5,246; Gold Coast 2,800; Sierra Leone 718; Belgian Congo 18,680; French West Africa 19,061; French Equatorial Africa 4,463. Angola alone has any considerable population classed as European (30,000) but this includes persons of mixed blood.

torate; in 1886 a charter was granted to the Company, which now took the name of the Royal Niger Company. Until 1900, when political control was transferred to the Crown, the Chartered Company was responsible both for the civil administration and for the development of trade. The Company, with limited resources, was, despite its best endeavours, never able to extend its administration over the territory as a whole; a short railway was constructed from Lagos into the interior;¹ but it is true to say that its influence was chiefly felt along the main trade routes on the rivers. Even after the transfer of government, much remained to be done in the pacification of the country, and it was not until after 1906 that the phase of internal economic development could begin. The fact remains that for a capital outlay of about £1,000,000 the largest British colony in Africa was added to the Crown.

Railway development has greatly increased the trade of Northern Nigeria, which, compared with that of the southern oil rivers, was in earlier years negligible. The main agricultural export of the north is groundnuts. Cotton is grown mainly for consumption by the local industry, spinning and weaving by hand, but in recent years there has been an increased export. From the south the important exports are mainly palm oil, palm kernels, and cocoa, while cotton is also grown. Of a total value of all exports amounting in 1935 to £12,049,643, that of groundnuts amounted to £2,092,590, of cotton to £879,925, of palm oil to £1,656,159, of palm kernels to £2,245,004, and of cocoa to £1,583,827.

Nigeria has not proved to be highly mineralized; its chief mineral exports are tin, in the mining of which some 30,000 natives are employed, and some alluvial gold. Tin and gold together form on the average about 16 per cent. of the total exports. Apart from the tin and gold mines,² and one or two small estates of oil palms in the south, European enterprise is confined to trade and commerce. The Moslem population of Northern Nigeria was already accustomed, before trade was opened from the south coast, to receive certain European imports brought to it by caravan across the Sahara. The great markets of Kano, Sokoto, and other towns were already important centres of distribution of local

¹ See Chap. XXIII, p. 1584.

² See Chap. XXII, pp. 1500 ff.

manufactures. The trade from the coast under the Royal Niger Company's administration had, despite provisions in the Charter, become in effect almost a monopoly of the Company, and it was the complaints of rival British and foreign traders which, added to friction with the French on the northern frontier, stimulated the government to take over political control. After the transfer, the Company reverted to the position of an ordinary trading concern, but it has retained, directly and indirectly, much of its earlier importance, and its more recent association with the Lever interests tends to make the trade in the territory in some measure dependent upon one of the chief consumers of the country's most important exports.

The history of European contacts with the Gold Coast is longer than that with any other African territory south of the Sahara. Economic development began long before pacification was completed by the final relief of Kumasi in 1900.¹ The gold mines had been famous since the fifteenth century; modern equipment and European methods were introduced in the seventies. But transport facilities did not exist, and transport costs absorbed all profit. A brief boom was followed by a period of stagnation until the completion of the railway line to Tarkwa in 1901 and Kumasi in 1903.²

The most valuable export of the Gold Coast for many years past has been cocoa. By 1935 its value was £5,204,000, more than twice that of the gold production. In 1900 the export was still not more than 536 tons. In 1914 this had risen to about 53,000 tons, and by 1935 to 269,000 tons, about half of the world's output. While this trade depends greatly upon transport facilities, and requires the help of a European marketing organization, the cultivation and the earlier stages of marketing remain almost exclusively in native hands. Of other agricultural exports the largest are those of palm oil and of timber. Neither of these is, however, comparable in importance with that of cocoa.

Sierra Leone developed slowly during the first half of the nineteenth century into a self-supporting and even moderately prosperous colony. Its area was extended considerably during the sixties. As late as the eighties, however, there was serious conflict with the

¹ See Chap. IX, p. 466.

² See Chap. XXIII, p. 1586.

native tribes, mainly in relation to slave trading, which culminated in 1898 in a rising of the Mende and the massacre of missionaries and native officials. After the suppression of this rising, peace was more consistently maintained, and economic development became more rapid. The building of the railway was begun in 1896, and completed to the Liberian frontier by 1905. It did much to stimulate trade, but this, if only because the population is far smaller, has not reached the scale of that of Nigeria or the Gold Coast. Of agricultural exports, that of palm kernels is the largest, and has fluctuated in recent years around £500,000, though ten years earlier it exceeded £1,000,000. Exports of palm oil, kola, ginger, and pissava add about £150,000 in a normal year. Mineral production is of considerably greater importance, and was valued at £1,249,695 in 1936.¹

While mining undertakings have here, as elsewhere, been a matter of European enterprise, the growing of export crops has been almost entirely in native hands. After prolonged discussions an ordinance² allowing concessions of land to Europeans for the erection of oil mills was passed, but little advantage has been taken of it.

These three British West African territories, and the small colony and protectorate of the Gambia, contained in 1931 a population of about 25,000,000, of whom less than 10,000 were Europeans. Of this total only about 175,000 were directly employed by European individuals or concerns, including about 88,000 engaged in mining and some 23,000 employed on the railways. But this relatively small total by no means indicates the extent of the absorption of the native population into the European economy, as large numbers are engaged in the cultivation of cash crops or even in working for others so engaged. The total exports of these territories amounted in 1935 to a little less than £1 per head of population, and of this about 26·4 per cent. was the value of minerals. If comparison is made with the East African group of territories other than Northern Rhodesia, the export per head is slightly higher and the dependence upon minerals markedly higher in West Africa. The remaining East Coast territories

¹ See Chap. XXII, p. 1503.

² Palm Oil Ordinance, 7 of 1913. See also Chap. XII, p. 781.

derived in 1935 no more than some 7·2 per cent. of their exports from minerals.

Of all the West African territories, the Gold Coast, with an export in 1935 of over £3 per head, can, despite the absence of any sufficient statistics of internal trade, be regarded as comparatively the richest. An attempt has been made by Mr. Cardinall, the Chief Census Officer, to estimate its national income in 1931. His calculations would seem to have involved a by no means inconsiderable element of double counting, but if due allowance be made for that, it would nevertheless appear that the annual income may have been in the neighbourhood of £13 per head. That figure, if it can be substantiated, would indicate that the average income is probably higher than that of India, and not considerably inferior to that of some of the eastern European countries.

French West Africa never shared in the policy of large-scale concessions which distinguished the early history of Equatorial Africa and the Belgian Congo.¹ The prevailing feature of the country is the relatively low density of the population; the policy of the administration has mainly been directed to improving the means of communication, for which it has borrowed large sums of money,² in order to overcome the obstacle presented by the scattered character of the population. Its chief export is groundnuts, a purely native-grown product; the marketing is being increasingly undertaken by the *sociétés de prévoyance*. Of recent years greater attention has, however, been paid to the production of coffee, bananas, and palm oil from the Ivory Coast, for the development of which a number of concessions of land, though none of them of the nature of large estates, are now being given to Europeans. In Equatorial Africa the régime of large concessions practically came to an end when the forest rubber ceased to command a market. The density of population is lower than that of French West Africa, and, save for the facility offered by the connexion of Ubangi-Shari with the Congo, Equatorial Africa is ill provided with communications. The territory has larger reserves of marketable timber than any of the French colonies. Of late years the admini-

¹ See Chap. XII, pp. 782 ff. See also S. H. Roberts, *History of French Colonial Policy*, 1929, vol. i, pp. 348 ff.

² See S. H. Frankel, *op. cit.*, chap. v, p. 335

stration has pursued an active policy of stimulating native production, notably that of cotton and coffee, and, as in French West Africa, a number of small concessions are being made to Europeans in the coastal area; but in 1935 timber still formed 60 per cent. of the total exports, which were in value about equal to those of South-West Africa.

In the Belgian Congo also the period of exploitation by holders of large-scale concessions came to an end with the decline in the demand for forest rubber, though a certain number of these concessions still remain, and in addition the administration in 1911 gave to the *Société des Huileries du Congo Belge* a large concession for the development of the palm-oil industry.¹ The non-official Europeans resident in the country, numbering about 7,000 in 1934, are mainly engaged in the management of the concessions, in mining and the like. There is in Belgium a certain amount of feeling in favour of attempting a policy of European colonization, particularly in the Kivu area,² but the *Commission des Colonies* has consistently reported to the senate against any scheme of this nature,³ and the opinion of local authorities in the Congo seems also to be strongly against it. One of the distinguishing features of the Congo economy is the manner in which the very large sums expended on the development of communications and mining have been financed.⁴ The majority of the companies operating in the Congo are controlled by four financial groups, of which the largest is the *Société Générale*; the capital of the companies it controls is 4,800 million francs, and the significance of its connexion with the Congo lies in the fact that the Belgian Government has a share in its finances. The investments in the Congo form, in fact, an important feature in the government *portefeuille*. It is also of significance that the most profitable of its investments are in mining. It would indeed appear that, with the exception of the mining investments, much of the outlay of Belgian capital in the Congo has yielded disappointing results; the railways, as shown elsewhere,⁵ have been largely dependent on their government

¹ See Chap. XII, p. 793, and Chap. XIII, pp. 919-20.

⁵ See Chap. XXIII, p. 1593.

guarantees; and inexperience of colonial conditions has led to much waste of money in other directions. The situation has been saved by the success of the mining industry; minerals now form about 60 per cent. of the exports. The administration is now endeavouring to stimulate peasant production, especially of cotton and coffee, and this seems indeed to furnish the most promising line of development for the Congo. The disadvantages of distance and of physical conditions are such that only crops produced at the minimum cost can compete in the world's markets. It is estimated that there are about 253,000 natives working in different ways for Europeans, or about 2·7 per cent. of the population.

The introduction of a régime of concessions, or of the 'plantation' economy, in British territories, and more particularly in the West African territories, has from time to time been strenuously advocated. The grounds for this advocacy have been two. In the first place it is pointed out that in few cases do these territories possess any natural and permanent monopoly of their products, and there is a real danger that if the quality of the product grown is not as steadily improved as scientific knowledge permits, the export trade will be progressively lost to foreign competitors. On this point it has been argued on the other side that in the case of products whose quality is not vitally affected by the immediate treatment after collection, the absence of overhead costs and the opportunities in time of depression to fall back upon subsistence agriculture, may well make it possible for native growers to produce more cheaply, if less scientifically, than the estates. The balance of advantage may often turn upon the ease or difficulty with which native growers can be taught by an Agricultural Department the latest knowledge and technique as regards the choice of plants or trees, the method of cultivation, and the prevention of disease.

The second ground on which the system has been advocated is concerned with the operation of factories and mills for processing the output. In some cases, such as that of palm oil, the method of extraction can make a very great difference both to the percentage of recovery and to the value of the product. It is said that by machinery a recovery of some 85 per cent. of the pericarp oil is possible, as compared with some 50 per cent. by native methods. Moreover, since the development of free fatty acid can be almost

completely prevented, and it may be used therefore for edible purposes, the oil from the factories will ordinarily command a premium over the native product. But a factory, to work efficiently, must have a regular and assured intake of fresh produce to be processed. It has not proved practicable, it is said, to depend upon the uncertain deliveries of native growers or collectors of wild produce. On the other hand to make contracts with natives for delivery, and to enforce them where necessary by fines or imprisonment, has before now degenerated into a scarcely concealed form of slavery. The solution, it is argued, is to permit the establishment of estates which can provide a sufficient minimum basic output to the factory, while relying upon natives for the remainder.

This solution depends, however, upon the assumption that natives, unwilling to work regularly while their own masters, will voluntarily agree to accept estate labour for wages. Mr. Ormsby-Gore, in his report on his visit in 1926 to West Africa, when referring to the proposed concession of land to the Lever interests, suggested that it would not be possible to secure regular delivery of produce to an oil factory without some element of compulsion.¹

'There can be no doubt that the system which obtains in the Congo does involve not only monopoly rights, but also elements of compulsion; and the trouble with compulsion in any form is that it is only successful in the long run if it is carried out consistently and completely. It is no use imagining that you can continue a voluntary system with a small element of compulsion. Any such scheme breaks down at the point where you are not prepared to go further with compulsion.'

That a considerable measure of compulsion was necessary in the earlier days to provide a sufficient labour force for the concessions in the Congo is beyond question.² The régime of direct compulsion is, however, now ended; if there is any pressure applied, it takes the form of allowing the concessionaire a monopoly of purchase of all fruits collected within a defined area, at prices fixed from time to time by the state. The extent to which a system of this nature may be objectionable will depend on the manner in which the state interprets its obligation to safeguard the native.

In dealing with the problems arising in regard to agriculture,³

¹ *Report by the Hon. W. G. A. Ormsby-Gore, on his visit to West Africa during the year 1926*, Cmd. 2744, p. 108. ² See Chap. XI, p. 647. ³ See Chap. XIII, p. 980.

some observations have been made on the extent to which the necessity for exercising a choice between a peasant and a 'plantation' system can now be said to form a practical issue. If it exists, it can, as was pointed out, apply only within a limited field. It may be noted that, where the difficulty lies in providing natives with the necessary plant for processing, a partial solution has been found in the use of co-operative methods which enable producers themselves to own and control the processing plants. But if the latter are to work efficiently, even if owned by a co-operative society they must rely upon a regular intake of raw produce, and in many parts of the world co-operative societies have found it necessary to make binding contracts with their members for exclusive trading. If such contracts are less onerous when made with a co-operative society, or if membership of such a society can make regular work and the loss of a casual freedom of existence less irksome, a way out may thus be discovered. But the fundamental fact remains that, as the monopoly of certain tropical products disappears, African natives must learn by painful experience how severely a competitive system punishes those who will not adopt the most efficient technique of production.

More recently another line of action has been followed. It has been sought to develop what has been termed a tripartite collaboration between the state, private enterprise, and the native. This solution is well illustrated by the scheme for the development of the Gezira area in the Sudan, which has been described in detail elsewhere.¹ A lease of the land which was to be irrigated was taken by the state, and the control of cultivation and the provision of various services, including tractor ploughing and ridging, was entrusted to the Sudan Plantations Syndicate. The subordinate tasks of cultivation and picking are left to tenants, in whose selection preference is given to the original right-holders in the land. They receive a fixed share of the proceeds of the sale of the crop produced, and also have land for subsistence cultivation. A somewhat similar plan for the co-operation of the state and the cultivator upon a share-farming basis is to be found in the schemes for the development of the Niger valley in French West Africa. Here, however, there is no separate syndicate carrying some part

¹ See Chap. XV, pp. 1053-5.

of the risks and responsibilities, and the government performs all the services of which the cultivators are not capable, selling the crop, and paying a share in it to the grower.¹

It will be clear that the element of voluntary collaboration is not very easily recognizable in either of these forms of association. They have, it is true, the merit of affording an effective means of securing the technical improvement of native methods of agriculture and marketing. But both examples owe their origin to unusual circumstances; in neither case could the administration have developed the settlement of the area brought under irrigation, or ensured a return on the heavy outlay incurred, unless it had secured an effective control both over the distribution of the land and the methods of cultivation. If similar systems come under consideration elsewhere, it is well to realize that their success involves either a strong measure of control (for the maintenance of which the only effective sanction is the dispossession of the cultivator) or voluntary co-operation to an extent which is only likely to be attained where a population is surplus to the land available, or the profits of cultivation so attractive as to outweigh other considerations. It must also be realized that there are always certain potential difficulties attending government enterprises of this nature. If the capital required is raised by loan, subject to fixed interest charges, there may be a further extension of that inflexibility of government expenditure, which in the case of railways has already proved a considerable handicap to other developments. It is one of the chief virtues of a system of private enterprise that in times of depression, or in cases of failure, the investor receives a diminished dividend. The risks involved in African enterprises are considerable, and do not disappear by the transference of responsibility to a government. It is only if the financial stability of a government is assured that it can safely involve itself in considerable undertakings of this kind.

III. THE NATIVE ECONOMY

(a) *The Union of South Africa and the High Commission Territories*

Thus far the types of economic organization considered have been fundamentally European in character, modified so far as

¹ For a discussion of various systems of this nature see H. Martin Leake, *Land Tenure and Agricultural Production in the Tropics*, 1927.

is necessary to facilitate the introduction of African workers or growers of cash crops for the European market. It remains to consider the economic developments which have been built upon a foundation not of the European but of the native organization, and the changes in the latter which have been brought about through changing circumstances. Many of the problems of the relation of the old economy to the new in South Africa were inevitably discussed at an earlier point, when the growth of the modern economy was under consideration. It became apparent that any native economic policy, designed to improve standards within the more primitive economic system, must start from certain assumptions regarding both the immediate and ultimate parts which natives will play in the general economy of South Africa. Differences of opinion, both among economists and among administrators, spring mainly from differences in their assumptions; and these assumptions involve questions of the political and sociological relations of the two races at least as difficult of solution as those that concern their more immediately economic relations. Any general economic policy must assume a view regarding the future independence or interdependence of the two economies. Is the native economic system a transitional survival, that requires to be kept in languishing existence until the growing modern system has completely replaced it and the two economies have become one? Or is there a permanent place in South Africa for a separate, segregated, native economy, having certain inevitable contacts with the more modern system, but contacts comparable in scale and effect with those that exist between two contiguous nations? The wisdom of innumerable major and minor decisions must depend on the replies to these questions. But they are not the kind of questions to which this generation can give one binding and irrevocable answer that will guide policy in perpetuity.

It has been inevitable, therefore, that policy should be subject to change, reflecting the general outlook of each succeeding generation, and the alternating fears of shortage of native labour, and of excessive native competition.¹ Thus in times of trade activity and

¹ See H. M. Robertson, '150 Years of Economic Contact between Black and White', *South African Journal of Economics*, vol. ii, no. 4, 1934, pp. 403-25, and vol. iii, no. 1, 1935, pp. 3-25.

universal prosperity a general scarcity of labour on the one hand, and the lessened fear of competition on the other, have permitted native advance into new fields of activity. In times of depression, and more particularly of agricultural depression, fears have inevitably increased, and restrictions have tended to multiply. Policy has reflected also, to some extent, the rival ideals of those who believe that the welfare of the Bantu is best promoted by permitting freely his absorption into a general South African system, not only of economics, but also of culture, and of those, on the other hand, who believe in the preservation of Bantu culture by restricting the violence with which European culture immediately impinges upon it.

The Native Economic Commission of 1930 expressed the view that while the primitive subsistence economy meets the requirements of a community at a certain level of development, the money economy is in entire conflict with it and must ultimately disintegrate it completely.¹ But in the case of the Union there are particular reasons why the transition must almost certainly be protracted. The closer numerical balance between the two races and the existence of a large permanent European population, in contrast to the more temporary and migratory European population of the territories of Central and West Africa, makes it necessary that European interests shall be fully considered in framing policy. The divided political control of the labour-employing and of some at least of the labour-supplying areas must, moreover, render any unified plan difficult. The peculiar circumstances of the chief industrial area on the Rand make it difficult to envisage any complete scheme for the 'stabilization' in that area of a large native labour force, with its full complement of women and children, and the exhaustible nature of the gold resources makes the wisdom of such a vast concentration in any case questionable. But the fact that the period of transition must be protracted increases the need to consider some of the problems which the native economy now presents. To take only one instance, recent attempts to prevent the growth of an urbanized native proletariat and a consequent native unemployment problem have served to increase

¹ *Report of the Native Economic Commission, 1930-32*, U.G. 22, 1932, para. 9; see also E. H. Brookes, *The Colour Problems of South Africa*, pp. 111 ff.

the pressure upon the reserves. In any case many of the problems of native economic welfare in the reserves would appear to be too urgent to permit of postponement even for a comparatively short period.¹

The economic life of the native reserves to-day is far from being an unchanging survival of the subsistence economy which existed when the Bantu first came into contact with the European.² In that economy exchange had no regular place, though on occasion a less skilful worker might barter grain for the product of a more skilful, and specialists, such as ironworkers, were paid in grain or cattle. Again, though wealth was viewed in terms of cattle, its accumulation was restricted, both on account of the obligations to which the possession of cattle gave rise, and because to attempt a private accumulation was to usurp the functions of the chief. But even before political sovereignty over the Bantu was claimed or exercised, European influences made themselves felt. At an early stage periodical fairs were held to which the Bantu brought their saleable property, such as ivory, cattle, hides or gum, and exchanged it for copper wire, axes, knives, beads or buttons.³ Before long traders began to penetrate into the native areas, trading posts were established, and the fairs died a natural death. The competition of trade goods soon began to destroy such native industries as existed. But their purchase, and the payment of taxation, inevitably required a compensatory sale. At first, ivory, hides, and gum played the most important part, but by degrees accumulated stores of these became exhausted, and other exports had to be found. Social customs and other restrictions prevented cattle-trading on a large scale,⁴ and the African thus came to depend largely on the sale of his crops and of his own labour for obtaining money for the purchase of imported goods.

The large-scale export of native crops has only developed during comparatively recent years. Nor is it everywhere possible, owing to the overcrowded state of some reserves and of some of the High Commission Territories, and the growing numbers of persons dependent in the main for food upon them. In Swaziland, for example,

¹ See Chap. XII, pp. 803 ff.

² See Chap. XIII, pp. 884 ff.

³ I. Schapera, 'Economic Changes in South African Native Life', *Africa*, vol. i, no. 2, 1928, p. 178.

⁴ See Chap. XIII, p. 882.

'the foodstuffs grown by Natives are only about one-fifth of their requirements, the remaining four-fifths being supplied by European farmers and by traders who import grain from the Union'.¹ Bechuanaland ordinarily imports mealies and kaffircorn which may be roughly estimated at from 5 to 10 per cent. of the total consumption. Basutoland, while still a very considerable net exporter of maize in years of good harvests, has imported large quantities in years of drought such as 1933. Thus an increasing emphasis has necessarily been placed upon the sale of labour as a means of purchasing imports and of securing the means of paying taxation. The growing pressure of industrial competition from low-paid native labour, from which the poorer sections of the white community have suffered, has been largely a consequence of the difficulties which the natives in their turn have encountered in expanding their own agricultural output sufficiently to feed themselves and to provide saleable exports.

Some idea of the important part played in the present economy of the native areas by the sale of labour can be obtained by roughly calculating the balance of payments in Basutoland. Other territories, or one of the Union reserves, might perhaps have yielded more interesting and typical information. For Basutoland is better placed than most, both in area per head of population,² and in the possession of a valuable export of wool. But none of them provides sufficient statistical material even for an approximate estimate. In 1933, visible imports into Basutoland amounted to about £643,000. Invisible imports, such as pensions and remittances, may be estimated to bring this to about £670,000. Visible exports were a little over £330,000. Thus invisible imports, including the value of all forms of remittances from labour working outside the territory, must have accounted for about £340,000, a little more than the total of visible exports. This figure is reasonably consistent both with what is known regarding the approximate total of wages paid to Basuto workers at the mines, and with the remittances made by them and other workers outside the territory during that year. The total of wages earned by 31,207 workers at the gold mines may be estimated at about £1,200,000. There were in addition some 30,000 others

¹ *Annual Report on Swaziland, 1933*, Colonial Report, 1694, p. 17.

² *Report on the Financial and Economic Situation of Basutoland*, Cmd. 4907, 1935, p. 33.

working in agriculture and miscellaneous labour, and a further 45,000 who had gone abroad on visiting passes. Though their wages were almost certainly much lower on an average than those of the men working at the mines, the total earnings must have been substantially in excess of £1,500,000. Remittances, repayments of advances, compensation payments, and deferred pay, chiefly from the mines, may be estimated approximately at £260,000.¹ To account for a further £80,000 as brought back by returning workers is not improbable. The total benefit to the territory would, if it amounted to £340,000, be between 20 and 25 per cent. of the wages of those working outside. This figure is in close accord with an estimate made for Northern Rhodesia,² where the benefit was calculated to be about 22 per cent. of wages.

Of the exports of Basutoland, other than human labour, approximately 68 per cent. in 1933 was accounted for by wool and mohair, 14 per cent. by wheat, and 12 per cent. by cattle exports. In years of good wool prices, such as 1928, as much as 75 per cent. came from wool and mohair, and the total value of exports varies largely in accordance with variations in their prices. These two exports fell in value from approximately £750,000 in 1928 to about £530,000 in 1929. The effect upon the numbers seeking work abroad was immediate. In 1928 there were issued 53,878 passes to natives who wished to leave the territory in search of work. In 1929 the figure rose to 74,762. The effect was most noticeable in the number seeking agricultural work and general labour, which increased by over 17,000. The continued fall in the price of wool in subsequent years, until wool and mohair exports in 1931 yielded no more than £116,000, gave an added stimulus to the search for work. It is, indeed, difficult to conceive how the present economic system of South Africa could operate, if it were not able to depend upon the unique inverse activity of gold, which makes it most urgently demanded, and its real value highest, in the depth of a depression.

The problem of the adequacy of the reserves has already been considered above.³ It is clear that the general trend of native

¹ *Report*, op. cit., Cmd. 4907, 1935, pp. 36-7.

² *Modern Industry and the African* (ed. J. M. Davis), 1933, p. 179.

³ See Chap. XII, p. 805.

life is now towards European civilization, and that the possibilities of the reserves must be judged by the opportunity which they afford to achieve that standard, and not by their ability to provide some improvement of the conditions hitherto associated with tribal life. But judged by the European standard, the ability of the existing reserves and the extensions now in contemplation to support the present native population is doubtful, even when allowance is made for the improvements in native agriculture, which are urgently needed. The consequences of the present limitations of native agricultural activity are twofold. In the first place, the native population now consumes, it is estimated, 8,000,000 bags of maize more than it produces,¹ and it is obliged to pay for this in the main by selling its labour outside the reserves, in the mines or towns, or in agriculture. Thus the proportion of natives living and supporting themselves in the reserves is diminished, and the competition of their enforced labour with the poor white section of the community is enhanced. In the second place, as a larger part of native incomes is spent upon the purchase of foodstuffs, the surplus available to buy other merchandise is reduced. Basutoland, for example, was able to buy over £1,000,000 worth of general merchandise in the prosperous years 1919-20. Purchases were over £750,000 in 1923-4 and in 1927-8. They had fallen to little over £400,000 in 1932, and after reaching about £363,000 in the famine year 1933, recovered to about the 1932 level in 1934. In Bechuanaland purchases were over £237,000 in 1929 and under £119,000 in 1933. With the precise causes of these declines we are not for the moment concerned. The figures serve to show that there is a considerable native demand for such merchandise, which at present goes largely unsatisfied. The question therefore arises whether the white community can derive more benefit by competing with native agriculture in the growing of native crops for native consumption, or by allowing the native to grow his own foodstuffs, thus setting free native purchasing power to buy manufactured goods. Judged purely from the economic standpoint it would seem that the relative advantage of the European is considerably greater in industry than in agriculture,

¹ See Chap. XII, p. 806. See also J. M. W. Grosskopf, *Weltwirtschaftliches Archiv*, Oct. 1933, p. 436.

and that the benefit to the industrial community would outweigh any loss of agricultural markets.

But even if additions to the reserves of the Union may be a necessary condition of the stabilization therein of the native community, and of any sufficient improvement of the standards of native life, it is urgently necessary that better use shall be made of the area that is already available. The more technical problems of agricultural improvement, and the many difficulties involved, have been discussed in Chapter XIII. The resources available both for agricultural improvement and for more general purposes of native development and education will be considered below. Such limited resources as will be shown to be available cannot be expected to produce substantial results in any short space of time. The Native Economic Commission rightly sounded a warning against undue haste. But the present situation in the reserves is not in general that of impulsive reforms being pressed upon a conservative majority. Rather are the reforms failing to keep pace with public demand for them, and the difficulties of stabilizing a contented population in the reserves spring largely from their inability to provide those mental and material enjoyments that the travelled native has now begun to demand. It is an almost necessary condition of the successful application of any policy of partial segregation that the reserves shall be enabled to make better and more attractive provision for their inhabitants.

Any sufficient raising of native standards of living in the South African reserves must come from one of two sources. It may come from an improvement in the technique of native agriculture making available both an increase of consumable products and an increased surplus for sale, and thus for the payment of taxation and for the purchase of imported goods. That agricultural improvements are most desirable none can question. But that such improvements can by themselves achieve the end in view is more open to doubt. Family budgets analysed for the Native Economic Commission indicated that the existing cash surplus on an average holding might be as great as £4 1s. 0d. or as little as 15s. 1d. For the Transkei, an average of £2 12s. 6d. was estimated; but it presupposed a price for mealies higher than most natives were likely to obtain in practice. It was argued by Mr. S. G. Butler, formerly

Principal of Tsolo Agricultural School, that by better farming this surplus might be increased to about £13 14s. 6d. Subsequent experiments would, however, suggest that this figure is too high,¹ and like the former figure it assumes a high price for mealies sold. It is difficult to make any comparable estimates of expenditure. Taxation in the Union will ordinarily absorb 30s. Blankets and clothing may require another £2 to £3, a 'dressed' native, or a Christian, requiring substantially more than a pagan. Beyond that, agricultural tools and implements, and such items as paraffin, matches, soap, sugar, tea and coffee, and pots and pans, absorb any residue. It is clear, however, that even if the surplus can be raised from some £2 10s. to £10 it will not easily suffice to meet the more urgent needs, and in addition permit of the payments of school and church fees, for better clothing, for improved furniture and household equipment, and the many other small improvements that natives with experience of town life are not unreasonably beginning to desire.

The second and alternative source of improved standards is a gradual increase of the division of labour and of the exchange of goods, so that instead of obtaining the means to satisfy their wants by the sale of surplus agricultural production, the natives themselves make directly some of their requirements. It has been an unfortunate consequence of African contact with Europeans that instead of being modified and improved, as were for example the early British goods by contact with the products of the Roman invaders,² native handicrafts have been with a few exceptions almost exterminated, and their place taken by imported goods paid for by labour or agriculture. The growth of industrial specialization, with its accompanying development of technique, is the road by which the western nations have gradually come to their present position of wealth. The increasing contacts during the passing centuries permitted from time to time great advances, as a technique developed abroad was transmitted, sometimes as the result of conscious policy, sometimes through wholesale migrations of skilled artisans to other countries, under the pressure of religious

¹ M. Hunter, *Reaction to Conquest*, 1936, p. 142.

² See R. G. Collingwood and J. N. L. Myres, *Roman Britain and the English Settlements*, 1936, p. 227.

or political persecution. But the closely parallel development of the European nations made such transmission relatively easy. A new foreign technique seldom, if ever, required a social structure so fundamentally different from that which already existed, that the community was unable to undergo the necessary process of adaptation.

The contacts between primitive native economies and Western capitalism are, on the other hand, essentially catastrophic. The primitive economy is incapable of adaptation to the new technique at one move. The problem is, then, whether it shall collapse completely and be replaced by a new model, complete with the social and legal framework which modern capitalism postulates, or whether it shall be supported and safeguarded temporarily while it undergoes a series of modifications, embracing within a short period the long course of Western economic development.¹ If the fusion of the two economic systems into one is the destination of African development, then to do more than delay the collapse of the primitive economy is waste of effort. But if partial segregation is to endure for a long period, as would appear likely, an attempt to modify and develop the native economy is necessary.

Within the reserves themselves there are already some signs of a gradual increase of the division of labour and of the exchange of products. Formerly, as has been described above, each family was, as regards most of its needs, self-sufficient. A few articles requiring particular skill in manufacture, such as pottery, ironwork, and basketwork, were exchanged. But the specialist seldom earned more than a small supplement to his normal income from agriculture. In recent years the situation has changed materially. In Pondoland, for example,

‘with European contact and the introduction of money has come a great increase in the circulation of goods, and consequently the necessity of accumulating goods which may be exchanged for other goods. Money has so penetrated and been absorbed into Pondo culture that it is commonly used in transactions between Pondo. In each district there is a standard cash price for such pottery, basketwork and woodwork as is made. The price may vary between district and district. A particu-

¹ It must not, of course, be supposed that a necessary process of modification involves a passage through every stage through which the Western economies have passed.

larly well-made article will command a higher price, but there is a recognized standard price . . . beer, and meat, which formerly were always given free, are now sometimes sold.¹

These are indications rather of a beginning of native exchange than of its wide prevalence. The development of the money economy is hindered somewhat in South Africa by the comparative absence of organized markets and fairs for the exchange of native products. Trade has hitherto been largely in the hands of European traders scattered usually at intervals of some half-dozen miles. In 1932 they numbered in the Transkei alone about 650. Their main business is the purchase of native cash crops or products, and the sale of a wide variety of imported or South African factory-made goods.² They do a certain trade in the purchase and re-sale of grain to natives, but the grain is often repurchased by the same persons who had originally sold it, and such transactions are often little more than a means of securing cash to pay taxes in advance of earnings obtained by work at the mines or elsewhere. Much of their trade is done on credit, based either upon the security of cattle or upon the bond of some second person.

During 1935 a few native traders were for the first time, and experimentally, allowed licences to trade at a distance of at least two miles from the nearest European trader. They may perhaps contribute eventually to a general increase of the practice of the purchase and sale of native goods by natives for cash. The position of the European trader has in the past been fortified by the fact that he performs a variety of functions other than that of trading pure and simple. He recruited labour for the mines until the introduction of the 'assisted voluntary system'.³ He has provided in one way or another substantial amounts of agricultural credit. The growth of banks or co-operative societies, or of facilities in the way of markets for the direct disposal of products to the exporting merchants, may gradually lead to the decline of the importance of the European trading store. But for the time being at least the store holds an important place not merely in the economic but also in the social life of the reserves.

Markets for the sale of cattle are comparatively rare, not only in

¹ M. Hunter, *op. cit.*, pp. 139-40.

² E. S. Haines, 'The Transkei Trader', *South African Journal of Economics*, vol. 1, no. 2, 1933.

³ See Chap. IX, p. 652.

the Union but also in the surrounding territories. Where they have been tried, as at Nongoma in Zululand, they have been well attended, and there has been a considerable turnover, as many as 1,176 head being sold in two days. There would appear to be scope for further experiments in this direction.

(b) *The Rhodesias and East Africa*

The native economic problems of the territories other than the Union have much in common though in detail they differ greatly. In none of them is the problem of the inadequacy of land so acute as in the Union, and in none of them is the ratio of European to native so high. Thus neither the demand for native labour on the one hand, nor the pressure to work on the other, is comparable with that farther south. Agriculture remains the predominating occupation, and industrial work is a less important part of the whole. It is interesting to contrast the situation in Africa with that which exists in other countries.¹

In Africa as a whole, including those territories north of the Sahara which are not covered by this Survey, approximately 74·4 per cent. of the population was in 1930 dependent upon agriculture. In the world as a whole the proportion was approximately 64·6 per cent. In the densely populated Asiatic countries it was close to the African figure, 75·1 per cent. In North America, on the other hand, it was approximately 23·1 per cent., and in Europe 36·7 per cent. If we take Europe and North, Central, and South America, which compose a more or less self-sufficient area utilizing modern agricultural methods, we find that approximately 39 per cent. of the population was dependent upon agriculture.

The first stage of improvement must come then from agricultural development.² Once a surplus is available there are, in the territories outside the Union, two alternatives open: the first to increase the agricultural production and exchange the surplus for manufactured goods, the second to withdraw resources from agriculture and devote them directly to the manufacture of the simpler products required. As to which of these processes will be more

¹ See *World Agriculture*, An International Survey by the Royal Institute of International Affairs, p. 3. For the sources of these estimates and for warnings regarding the uncertainty of some few components of them, reference should be made to that volume.

² See Chap. XIII, p. 960.

economical no generalization is possible. If agricultural efficiency can be stimulated, while craftsmanship lags, the comparative advantage may lie in selling agricultural products. But distances in Africa are great, transport costs high, and the residue left to the original producer small. If, on the other hand, by degrees, skill in making elementary products can be developed, the automatic protection afforded by the inward transport costs will be considerable.

By whichever of these routes the advance is made, the possibility of further improvement must depend largely upon the facilities which may exist for the transport and exchange of goods. 'The material development of Africa', wrote Lord Lugard,¹ 'may be summed up in one word "transport".' The transport of goods to their ultimate consumers requires not only the technical equipment to move them, but also the human organization of merchants, middlemen, and markets to deal in them, and to take over from the individual grower or craftsman the tasks of discovering where they may be profitably sold, and of financing their movement.

Thus the development of markets and of marketing facilities is, after the improvement of agriculture and transport, the first desideratum. There is, however, no systematic study available for Africa as a whole, or even for individual territories, of the methods of native trade, of the extent of the development of the exchange economy, of the extent of inter-local native trade in foodstuffs or goods, or of the extent of the use of money in trade between native and native. More detailed inquiry into this field would be most valuable.

The main essentials of the native economy of Southern Rhodesia are similar to those of the Union. The aim of recent governments has been to depend upon the native races for all unskilled labour, but, that apart, to regard segregation as 'absolutely necessary for the comfort and happiness of both races', not only territorial segregation, but also economic segregation sufficient to prevent economic competition between individual members of the two races.² The consequences of this policy in so far as it concerns native lands have been discussed elsewhere. It was there shown that in addi-

¹ *The Dual Mandate in British Tropical Africa*, 1929, p. 5.

² See Sir C. H. Rodwell, *Address to Conference of Superintendents of Natives and Native Commissioners*, 1927.

tion to defining areas for native occupation, further land has been made available for native purchase. Thus the attempts to better native agriculture are directed partly to the improvement of the traditional system of shifting cultivation, and partly to the inculcation of new ideas that can be followed on small holdings subject to individual tenure.¹

This problem has been made urgent by the rapid growth both of human and animal population. Since 1902 the human population has, if the earlier estimates can be trusted, more than doubled, and the number of cattle has increased almost thirty times. Since 1910 there has been a growth of over 50 per cent. in human population, and a more than six times increase of cattle. Drought in recent years has severely reduced the numbers of the latter in some of the more seriously overstocked reserves, but it is becoming increasingly clear that, here as elsewhere, if the African will not consume his cattle, his cattle will consume him. The Southern Rhodesian natives are less unwilling than are many others to sell cattle when a satisfactory market is open to them. An account of the extent of native trade in grain and cattle has been given in a previous chapter.² Attempts have been made recently to increase the range of cash crops by introducing the cultivation of cotton and groundnuts. It is too early to say how successful these experiments will prove.

Apart from agricultural education,³ attempts have been made to raise the standard of living in the native areas by the teaching of crafts, and from the purely technical aspect some success has been achieved. But, as in the Union, the absorption of these craftsmen has proved a difficult problem. The European demand for their services has reached, or almost reached, saturation point. To the more important end of raising native standards they cannot at present easily contribute. The employment of specialist craftsmen can develop only at a pace dictated by the slow growth of a more widespread practice of specialization and exchange, and of the progressive establishment of an economy based upon division of labour.

In the past such development has been somewhat obstructed

¹ See Chap. XIII, pp. 960 ff.

³ *Ibid.*, p. 964.

² *Ibid.*, *passim*.

here, as also in Northern Rhodesia, by the absence of monetary units of a size suitable to the needs of native trade. The recent introduction of a cupro-nickel currency of small denominations may help to encourage it. But it is clear that the almost complete absence of native markets and fairs, and of the widespread exchange of products which they stimulate, is a grave handicap to economic development, and it is to be hoped that it will be gradually eliminated.

The native economy of Northern Rhodesia has moved less far from the subsistence stage than that of any of the areas thus far considered. The absence of communications, the limitations on movement imposed by the tsetse, the relative poverty of the territory before the development of the copper mines, the distance from the main centres of employment in the Union, all contributed to postpone change until, in the last two decades, the demand for labour, first in Katanga and later in the copperbelt, brought about a sudden economic revolution. But even to-day the subsistence economy remains the typical and predominant feature, and trading relatively inconsiderable.

In both the Rhodesias, as in the Union, the bulk of the native trade was until lately in the hands of European stores. The Indian traders, who play so large a part in the commerce of East Africa, were here comparatively few in number. In Southern Rhodesia there were in 1931 only 777 Asiatic male wage-earners, of whom 343 were engaged in commerce. Their number had grown perceptibly since 1926. In Northern Rhodesia the total Asiatic population in 1931 was no more than 56. But they are beginning to play an increasingly important part in the organization of the native trade, and many of the native hawkers and shopkeepers are now little more than agents.¹ The European trading stores of Northern Rhodesia have been in the past more concerned with the sale of imported manufactures than with the purchase of native goods for export. This has been in part at least an inevitable consequence of a lack of cash crops capable of supporting the high transport costs consequent upon distance from the railway, or from any alternative means of cheap transport. During the last few years, however,

¹ *Report on the Financial and Economic Position of Northern Rhodesia*, Colonial 145, 1938, pp. 21 and 28.

new opportunities for the profitable sale of native produce have been discovered. In the neighbourhood of the railway they have developed cash crops and market-garden produce. For the more remote areas a trade in skins and beeswax¹ has been built up.

The trade even of the European stores has in the past been largely in the form of barter.

'Most European traders have made a practice of bartering trade goods for grain, thus securing to themselves a larger profit, and natives living at a distance from the railway have found great difficulty in obtaining cash for their produce. This state of affairs is unsatisfactory both from the point of view of natives and of the Government, and consideration is being given to the introduction of legislation prohibiting the practice. In the meantime, every effort is being made to encourage cash payments.'²

In addition to the European trading stores a considerable number of natives have possessed hawkers' licences. While some of these are natives regularly engaged in trade, there are many who have returned from work in Southern Rhodesia or elsewhere, bringing home their savings in the form of trade goods of which they wish to dispose. In the past, however, the number of hawkers has been swollen as a consequence of the high cost of native shop licences. Since there is no purpose in discouraging the more easily controlled village shop, a new system of cheap village-shop licences was introduced in 1936. No licence is necessary, however, for trading in native goods, and since the growth of the copper mines there has been a great extension of purely native trade. Honey, fish, tobacco, and a variety of other foods and condiments have been transported to the mines, partly by head-porterage, but mainly upon bicycles.

Though the general stimulus of activity in Northern Rhodesia has encouraged in these ways the trade in native produce, native manufacture is undoubtedly on the decline. The smelting of iron is moribund; the ubiquitous petrol tin has made pottery an almost forgotten art; the hand-loom has nearly disappeared. It is a regrettable effect of European contacts in Africa that an increase in wealth should thus destroy rather than stimulate local craftsman-

¹ See Chap. XIII, p. 891.

² Northern Rhodesia, *Native Affairs Annual Report*, 1935, p. 15.

ship. For it makes it increasingly difficult to resist the tendency of secondary industries, catering for the native market, to grow on the European model in the big urban centres, with inevitable repercussions upon health and welfare.

Throughout the remaining East African territories the Indian trader is responsible for a very large part of the whole native trade, but more particularly that concerned in the sale of imported goods and the collection of native products for export. The local trade, on the other hand, between native and native in foodstuffs and other local produce is mainly conducted through markets, and is largely in the hands of the women, who freely exchange their surplus products without need for any licence or permit. In Kenya there are great numbers of small markets of this kind, which occur as often as once or twice a week. The women will carry their produce several hours' walk to the traditional place of market, as much to enjoy the opportunity of meeting their friends as to secure profit from exchange. In these markets the bulk of transactions are by barter, and customary values exist at which one product is exchanged for another.¹ These markets for the exchange of native produce have become centres also for other purposes and other trades. They have been used as places for the establishment of ghee dairies and hide-curing depots. They are attended also by native hawkers or traders, selling imported goods of every sort and description. This trade is mainly in the hands of men, and is conducted chiefly through the medium of money.

These native markets are in many cases attended also by Indian traders purchasing native produce for export. They buy, as a rule for cash, but sometimes by barter, produce which is brought in either by head or to a less extent by cart or lorry. The traders in the smaller centres sell either to wholesalers in bigger centres or direct to the exporter. They are seldom very expert buyers, and the market is as a rule highly competitive. They fear to reject consignments because the trade will merely go to a rival. In consequence a large quantity of inferior stuff is often bought and mixed with better produce, lowering its grade and making it hard to sell. This practice has made it particularly difficult for Agricultural

¹ For accounts of such markets, and of the products exchanged, see R. C. Thurnwald, *Black and White in East Africa*, 1936, pp. 107-8, and J. Huxley, *Africa View*, 1932, pp. 176 ff.

Departments to improve quality and price. With this latter end in view, the Government of Kenya introduced a Crop Production and Live Stock Ordinance,¹ giving power to prohibit trading in produce of inferior quality. When this did not fully meet requirements, a system of inspection centres was substituted, to which all produce must be brought before being sold in a trading centre. The Native Produce Market Ordinance² gives additional powers to control and regulate native produce. Purchase may only be under licence. Exclusive licences may be granted for periods up to seven years for products or technical methods new to an area. The Governor-in-Council may prescribe minimum prices where an exclusive licence is granted, and barter may be prohibited. Rules may be made for the regulation of markets, including the restriction of purchase to specified places and times. This Ordinance has been applied to wheat, maize, milk, and butter.

The important part the Indian community play as traders has been described in the chapter dealing with the non-European immigrant communities. Of the total Indian population of Kenya, which amounted in 1931 to 39,644, of whom 17,749 were adult males, as many as 9,868 were occupied in commerce. Of other races, there were 1,576 Europeans, 866 Goans and 3,172 Arabs engaged in commerce. In Tanganyika the petty trade is likewise almost exclusively in Indian hands. Of a total Indian population of 23,224, there were 3,860 engaged in commerce. Since 1927 these traders come under a scheme of licences.

Both in Tanganyika and in Uganda the greater part of the collection and marketing of the native-grown cotton crop is in the hands of Indian traders. All the ginneries in the neighbourhood of Mwanza in Tanganyika are controlled by Indians. The markets in the Lake Province are so regulated that fair prices may be obtained by the native growers. They are forbidden to sell cotton except at licensed markets and to licensed buyers. Some of the markets are confined to ginners; in others the buyers are middlemen. The Agricultural Department declares a weekly price, based upon a standard formula relating the local price to price in the world markets.

In Uganda the purchase of cotton in the early days, after the first

¹ No. 3 of 1926.

² No. 28 of 1935.

introduction of the crop following the opening of the railway in 1902, was largely in the hands of itinerant Indian buyers. But a system of markets was soon established, and power-driven ginneries were built. The transport of seed cotton to the ginneries was at first largely by head, involving great waste of time and labour, but by degrees roads were improved and up-country ginneries multiplied. A collapse of prices in 1921 brought the government into active participation in the carrying and marketing of the crop, and led to an investigation in 1923 into the problems of the industry. In the following year a Cotton Control Board was established. By its recommendation permanent markets were created in the Eastern Province, and in 1926 a Cotton Ordinance, since amended in various respects, provided for the control of cultivation, marketing, and ginning. The increasing number of ginneries had made competition between them intense, and unauthorized increases of ginning capacity were forbidden. An attempt, not wholly successful and since abandoned, was made to diminish competition by the establishment of area cotton-buying associations, and the prohibition of movements of seed cotton out of their areas.

This competition of ginneries led to the development by buyers of facilities for the collection by lorry of cotton from the growers. While this has been a great gain to native growers, it has had the disadvantage of making more common the mixing of qualities and the spread of disease. To prevent this, cotton-growing areas have been divided into quality zones, and a system of licensing of lorries introduced, which confines their operation to a single zone. As it was realized that this would tend to encourage the creation of buying associations within each zone, power was taken to fix minimum prices, should it be necessary. The growing importance of the crop has now led to the establishment of a local market for cotton. Brokers have opened offices in Kampala and Jinja, but export is concentrated mainly in the hands of a small number of big firms.¹

As in Kenya, powers exist in Uganda under the Native Produce Marketing Ordinance, to regulate the conditions of sale of produce which is of economic importance. If the Governor 'declares' some district in respect of some particular product, no person who does not possess a licence may buy or export that product from that

¹ See H. B. Thomas and R. Scott, *op. cit.*, pp. 131-5.

district. The Ordinance also provides for the limitation of sales to recognized markets, for the requirement that purchases shall be in cash, and for grading and price-fixing. These powers have been used to control in certain districts the marketing of coffee, tobacco, simsim, and groundnuts.¹ The markets dealing in native food-stuffs and produce are less developed than in some other parts of East Africa. Though they exist in various towns and native centres, the trade conducted in them is said to be small.² The trade in imported goods is largely in Indian hands. The latter act as intermediaries between the wholesale business houses in Nairobi, Mombasa and other centres, and the native. The native hawker or stall-holder does only a small part of the trade. The government can control, under the Trading Centres Ordinance, the sites of stores to be set up by non-natives, according to the needs of the population.

(c) *West Africa*

In West Africa the progress of the exchange economy has proceeded very much further than in East or Central Africa. The Hausas in particular possess a far greater aptitude for commerce than do most of the Bantu tribes, and from the time of the slave trade there has been a hierarchy of middlemen linking the commerce of the ports to the interior. Apart from minerals the wealth of West Africa depends mainly upon natural products, in particular palm oil and cocoa, harvested by natives without the direct intervention of any European organization; the latter is concerned chiefly with the tasks of transport and with the final processes of marketing. The need for some means of handling the crops in the earlier stages of their movement from the grower to the final exporter has brought into existence a large group of native traders, but it is a matter of frequent complaint that the goods have to pass through too many hands, and that too small a share in the final price reaches the original grower. An improvement in their efficiency, and the elimination of those who are redundant, might do much to improve standards of living of the native population. But the final income of the native growers depends also upon the maintenance of a sufficient measure of competition to ensure them a fair

¹ See H. B. Thomas and R. Scott, *op. cit.*, pp. 142-3.

² *Ibid.*, p. 122.

share of the selling value. Already the limited number both of ultimate consuming undertakings, and of exporting agencies through whose hands the produce must pass, makes possible the fixing of prices for exports at a lower level than might prevail under more competitive conditions. In some cases they are being superseded by the growth of co-operative organizations for the more direct marketing of the crop.¹ It may prove to be an added advantage of co-operative marketing that it will strengthen the bargaining power of the grower as against the consumers and merchants.

Throughout West Africa the Syrians have in recent years come to take a prominent part in commercial activity; all over the Gold Coast, Syrian stores predominate. Besides trading in imported goods they are engaged in road transport and as brokers in the cocoa trade. They provide most of the money-lending facilities, from large-scale finance to petty pawnbroking.

In addition to facilities for marketing export crops, there are large and numerous markets dealing in local produce of every kind. This petty trade is, as everywhere, largely in the hands of the women. Both in Nigeria and the Gold Coast there is evidence of an increasing specialization of particular areas in particular crops, and internal trade in foodstuffs between one area and another. The coastal towns in particular are becoming dependent upon outside sources.

These marketing facilities are in part a consequence, in part a necessary condition, of a much more extensive practice of specialization and exchange than is to be found elsewhere in Africa. In the Northern Province of Nigeria, at the census of 1931, about 84 per cent. of occupied males whose returns permitted them to be classified were shown as engaged in agriculture and fishing, about 9 per cent. in manufacture, and under 3 per cent. in commerce and finance. The predominance of agriculture was to be expected, since even those who are partly engaged in other and more specialized tasks are often primarily subsistence farmers. An intensive census of a small sample of the population made it possible, however, to glean some information regarding these subsidiary occupations. Of 214,452 males of the chief tribes covered by the intensive census, 69,583 were unclassified, living on private means, retired,

¹ See Chap. XXI, pp. 1474-7.

or not gainfully occupied. Of the remainder, 80 per cent. were engaged primarily in agriculture, about 6 per cent. in manufacture, some 5 per cent. in personal service, and a little over 3 per cent. in commerce and finance. Of these, 43,159 had subsidiary occupations, of which 'manufactures' included 27,079, commerce and finance 4,935, and professions, &c., 3,278. A further 6,752, who had presumably been classified under manufactures, commerce, or some other service as a main occupation, showed agriculture as a subsidiary occupation. Of the women covered by the general census, as many as 493,863 out of 2,179,960 returned themselves as occupied in manufactures. Of these more than seven-eighths were spinners, weavers, or dyers.

For Southern Nigeria less detailed information is available. The returns, which are less reliable than those for Northern Nigeria, would suggest that the proportion of males engaged in agriculture is about 82 per cent., and that concerned with handicrafts about 4.7 per cent. For the Gold Coast no strictly comparable figures are available. But such details as are available show there also a gradual emergence of a class of craftsmen and traders depending for part at least of their livelihood upon the sale of their products and services.

The more highly developed economy of West Africa has resulted in a far greater degree of urbanization than is to be found elsewhere. In Nigeria as a whole, some 29 per cent. of the population was living in 1931 in towns of over 5,000 inhabitants; those of the Northern Provinces had grown by 38 per cent., and those of the Southern by 27 per cent., during the decade. Ibadan had an estimated population of 387,133, Lagos of 126,108, and Kano of 97,031.

(d) Native Economic Development

If we attempt to consider in more concrete terms the possible steps that may be taken to promote native economic development, it is important to remember that there are two main limitations to industrial progress. The first is ignorance of technique; the second is lack of capital. It is of little service to teach a technique which requires tools and equipment entirely beyond the purchasing power of the native craftsman. European teachers are, despite

themselves, often ill suited to teach African natives the rudiments of new crafts. For, apart from a few trades such as building and leather-working, in which handicraft still persists in Europe, the technique that requires to be taught is obsolete, or continues, as in hand-weaving, only as an artificial survival from a less mechanical age.

The African could in many cases learn more readily from association with Indian craftsmen, who practise as a living art the processes which he requires to learn and who suffer the same disabilities from lack of capital to buy expensive equipment. If Indian rather than European contacts had affected African techniques, we might have expected to see a development of the potter's skill and the use of the potter's wheel, the growth of cotton and wool spinning and weaving by elementary and simple methods, the improvement of metal-working and the introduction of the manufacture of brass-ware. Such trades, as practised in many parts of India, are not beyond the immediate capacities of African workers, and require little capital. If the scope of the contacts with Indian settlers could be somewhat modified, and become less commercial and more industrial, there is probably no country from which Africa could for the moment learn more. In the meanwhile, however, technical education rests largely, like all education, upon the shoulders of governments and of the missionary societies. In planning their work they will do well always to bear in mind the two chief difficulties of a native craftsman: first, his lack of capital, and second, his difficulty as a specialist in fitting into a society that is not yet fully specialized; and the importance therefore of developing a system of exchange *pari passu* with a system of specialization.

Any generalization regarding the industrial capacities of African peoples would almost certainly be misleading. That they are capable under careful European supervision of routine mechanical work in railway workshops and in the mining undertakings in the Belgian Congo and West Africa, is beyond question. They drive the trains on the railways of Nigeria and other British West African territories and in some of the French and Belgian possessions. They are becoming skilful, if somewhat erratic, motor-drivers and mechanics. They are by degrees acquiring some proficiency in the

building trades. In parts of British and French West Africa and the Congo an inherited craftsmanship has established a foundation stock upon which new techniques can be grafted, and the introduction of newer methods into the textile and wood-working trades is in no way prevented by lack of possible skilled workers. But in many other parts of Africa it would be idle to suggest that the ordinary tribesman yet possesses either an inborn dexterity or a quickness of intelligence that will enable him rapidly to master the use of new tools and the essentials of new methods. Mechanical education must go hand in hand with mental education, and the pride in good work and the sense of responsibility, which must underlie good craftsmanship, may prove more difficult to inculcate than the purely manual skill. But the effective limitation to progress may not improbably be found to lie less in the difficulties of developing the mechanical abilities of individuals than in those of creating the general environment in which they can be employed, and of training simultaneously and in proper balance men to fill the wide range of complementary and supplementary occupations for which modern industry calls.

Once granted the requisite technical ability and the requisite setting, it is clear that the further economic development of the native population, and the place that must be taken by European or other alien entrepreneurs, are closely inter-related with the problem of the supply of capital and credit to small borrowers in Africa. It is as owner and provider of capital, as well as of technique and knowledge, that the European plantation undertaking possesses an advantage over the native grower. It is from advantages in the terms on which they may buy, and the credit which they can secure, as well as from superior skill and intelligence, that the Indian or Syrian traders largely derive their predominance. Moreover, the transition from a shifting agriculture to a permanent mixed farming,¹ such as is being attempted in Nigeria and elsewhere, must progressively result in a need for capital for permanent improvements, such as buildings and equipment, and for agricultural credit to finance growing crops and for other similar purposes. But the problem of the supply of capital to natives in Africa is particularly difficult. Only a very small pro-

¹ See Chap. XIII, pp. 962 ff.

portion of the whole native population has yet reached a stage of education and responsibility which would make it likely that they would use credit wisely, and with a proper balancing of the consequences to income and outgoings.

For the moment any widespread development of facilities for the provision of capital and credit would probably be premature, and might well lead to the accumulation of debts incurred for extravagant standards of expenditure, such as have proved a very serious social and economic problem in India.¹ But there are, as was suggested in dealing with the subject of private rights in land, certain parts of Africa where a mechanism for the supply of capital must before long become desirable.

There is, however, one substantial obstacle to such developments. Capital for agriculture is ordinarily provided in one of two ways. Where there is a landlord-and-tenant system, a large part of the fixed capital is provided by the landlord. Where the farmer is himself the owner of his land, he borrows ordinarily by mortgaging it. In Africa there is, with few exceptions, neither a landlord class owning the land and able to invest in its improvement nor a class of individual owner-cultivators of the soil, and the individual tenure scarcely anywhere exists which would permit the land to be mortgaged and, if necessary, surrendered.² Thus it may not prove easy to develop a system of agricultural credit. Such credit as is at the moment available takes chiefly the form of cash advances against growing export crops which have been sold by contract to merchants. For the present this method of finance probably suffices, but where more elaborate equipment begins to require longer-term capital, African institutions, as now constituted, make it difficult to provide the necessary security.

These difficulties of the provision of capital raise a wider issue. If economic progress is to be made easy, it must operate in a social and legal framework suited to it. There are three pre-requisites to development. First, the existence of a law of property which will make capital-raising easier; second, the existence of a law of property which will give sufficient individual incentive; third, the existence of a law of contract which can be enforced with certainty. It has already been pointed out that in parts both of East and West

¹ See Chap. XII, p. 715.

² See Chap. XII, pp. 829 ff.

Africa the custom of communal land tenure is beginning to yield to one of individual holding, and some suggestions have been made regarding the form which title might take, if and when economic and social conditions render it advisable to recognize it.¹ But it need not follow from this that individual tenure is the only solution. If, for example, the tribal unit could become an economic as well as a political unit, raising capital against the value of the tribal lands, acting as a co-operative bank and selling organization, and taxing individuals through a rent upon their holdings, a rapid transition to individual ownership of land might possibly be avoided. But any such development assumes a roughly parallel progress of all the individuals in a given community. Some form of individual title is in any case necessary, as has been seen in Southern Rhodesia, where the rate of progress is not uniform, and individuals wish to break away and use more improved methods than their neighbours.²

Regarding the essential conditions for a sufficient incentive to stimulate individuals to undertake new activities, any dogmatic generalization would almost certainly be misplaced. In primitive societies direct incentive has sometimes been less effective than a traditional requirement for a generous reciprocity of gifts. In European conditions no system of incentives is usually to be found within the family itself. What incentive will in the long run prove necessary in African conditions, must depend upon the strength and persistence of family and tribal ties and the psychological consequences of increasing contacts with the more highly individualized European economy. In the towns and at the mines in the Union, and in the ports of the West African territories, it would appear that to an increasing extent individuals are coming to regard their earnings as related to their own activities and within their individual disposal. Remittances of money and the presents taken home represent usually, it has been seen, no more than a small proportion of the total earnings. The problem of the relation of ownership to incentive becomes more difficult when we consider the problems of saving and capital investment, which must become increasingly important. If an individual is to deny himself in the present, it is necessary that he should feel that only that

¹ See Chap. XII, pp. 868 ff.

² See Chap. XII, pp. 736 and 847.

group should ultimately benefit which has either shared in the thrift, or whose satisfactions he values equally with his own. While it would be premature to attempt to forecast with certainty the ultimate consequences of the need for incentives in an increasingly differentiated society, it is clear that its relation to the law of property must become of growing importance.

The need for an effective law of contract is obvious. If craftsmen are to undertake work of specialized character to meet the needs of a particular customer, they must be in a position to enforce the contract to pay for it. And where there is group ownership of wealth, it must be clear who may and may not be able to exercise control over it, to the extent of making contract to dispose of it. If a system of contracts is to be workable in the ordinary day-to-day business of native life, it must be enforceable in the native courts; but though it may be desirable to avoid the complications of European legislation, the matter cannot be left entirely to the vagaries of tribal custom. However simple may be the form which a law of contract takes, it must be uniform throughout the whole area in which contracts may arise.

The native economy of Africa is almost everywhere in a state of change. New knowledge, new markets, new contacts, new forms of transport, growing populations, the suppression of warfare, and a new division of labour between the sexes are all contributing to break down the old framework of social and economic life. The need to pay taxes, the opportunity to grow export crops, and the desire to buy imports, are bringing the African increasingly into contact with world markets. It is easy to regret the passing of traditional habits and systems, and to deplore many of the less attractive phenomena of progress. To attempt to resist these changes would be profitless. But to guide and control them is not impossible, and the ultimate forms of economic organization may depend largely upon decisions, as for example regarding the forms of land tenure, made at this stage. The administrations in Africa have an opportunity which was denied to the earlier British administration in India, not merely by the existence of the strongly entrenched social customs of India, but by the dominance of the doctrine of *laissez-faire* at the most formative period of British rule.

IV. PUBLIC FINANCES

The chief point of interest in a colonial budget is the relation between the overhead expenditure on general administration (including the payment of fixed interest charges) and the provision made for outlay on development. It is not, however, possible to distinguish accurately the amount of expenditure on the 'nation-building' services; a judiciously designed road programme may be more truly an item of nation-building expenditure than the opening of a series of industrial schools; and the liberal employment of Africans in the administrative services, or even in a commercialized department, may do more to advance their status than a large outlay on experimental farms. Even the fixed interest charges may represent capital expenditure on work which is in the best sense nation-building. In the accompanying table,¹ which analyses the estimated expenditure for 1936-7 in the British dependencies, some attempt has been made to distinguish in broad outline the figures of expenditure on 'economic development' and those on 'social services'. These figures must be examined in the light of the observations just made, and for practical purposes it is also advisable to consider the two heads together, since the distinction between them is little more than conventional. They also need modification in one respect. Thus, in the case of territories such as Nigeria or Tanganyika, it is necessary to add also the figures of expenditure by the native treasuries; in Nigeria, for example, the expenditure on the combined heads, namely 29.3 per cent. of the total, must be increased on this account to about 39.3 per cent. There is, as will be seen, a considerable divergence in the scale of expenditure of the class under discussion. The low figure for Northern Rhodesia is partly explained by the high level of debt charges, due largely to expenditure on the new capital. In Kenya the proportion was 36.5 per cent., in Uganda 40.9 per cent., and in the Gold Coast 44.3 per cent. But with large populations to administer and a small total revenue, the expenditure per head upon social services and economic development combined is in most cases very small by European standards. Social services

¹ Both the figures and their distribution between different categories are derived from *An Economic Survey of the Colonial Empire*, Colonial 126, 1935.

TABLE XIII
Analysis of Expenditure, on the Basis of the Estimates for 1936-7

Territory	(1) Deficit of self- balancing de- partments		(2) Debt charges other than railways		(3) Administra- tion		(4) Economic de- velopment		(5) Social services		(6) Defence		(7) Non-effective pensions, &c. * This does not include expenditure for these purposes from native treasuries. In Nigeria there was a total expenditure by treasuries of about 1.3s. per head of population of which about 0.5s. was devoted to economic development and social services. In Tanganyika expenditure from treasuries on development, &c., was only equal to about 0.2s. per head. In Nyasaland it was slightly less.

cost £6.15 per head in Great Britain in 1934. In the estimates for 1936-7 it is highest in Zanzibar at about 11.9s. per head. It is lowest in Nyasaland and Nigeria, where, including expenditure from native treasuries, it is a little under 1.9s. per head. It is less than 2.5s. per head in Sierra Leone and in Tanganyika, and under 3.5s. per head in Northern Rhodesia. As the revenues of the territories improve, it may be expected that the ratio of expenditure on these two combined heads will steadily increase. One of the difficulties of colonial finance lies in the fact that it is necessary to begin by constructing at considerable expense (and often with the aid of loan capital) the framework on which social advance must subsequently be built. Once the framework is constructed, administrative charges do not necessarily expand in proportion to the advance of the territory. If there is an increase of purely administrative expenditure in the future, it is likely to be mainly in the expansion of the judicial or police services, or the creation of Land Survey or Registration Departments. But this expenditure is not likely to be such as seriously to increase the ratio of the administrative to other heads, while the development and social service heads will, apart from the normal increase in their share of general revenues, receive an indirect addition from the growth of local government institutions with power to raise their own resources.

The financial position of the different British territories reflects closely their relative economic strength. The circumstances of the Union differ so fundamentally from those of the newer and less populated colonies that it will not here be discussed in detail. The existence of the gold-mining industry has provided it with the taxable capacity requisite to its ordinary needs; it is noteworthy that special mining taxation was responsible in 1935-6 for 26.95 per cent. of the revenue, and the taxation of mining incomes for a considerable additional share of the whole. The total tax revenue of the Union Government and of the provincial administrations has risen from £9,700,000 in 1913 to £36,700,000 in 1935. The total debt, as was pointed out in the last chapter,¹ has risen during this period from about £119,000,000 to about £248,000,000, but the increase in the foreign debt has been small, and more than half of the whole is now internal.

¹ See Chap. XIX, p. 1324, and S. H. Frankel, *op. cit.*, p. 176, Table 35.

The finances of South-West Africa have always been difficult.¹ In the years of German administration lavish help was given to the colony. From 1904 to 1910 the Imperial Government met annual deficits on the administration to the extent of over £14,000,000, in addition to the war expenditure between 1904 and 1908 of over £23,000,000. After 1908 the Imperial Government paid at first the whole and later two-thirds of the cost of garrison and police services. The revenues of the territory in the early years were meagre, but after the discovery of diamonds in 1908 they increased considerably. When the Union Government received the mandate in 1920 the deficits of the occupation period, 1915-20, were not made a charge on the territory, and for a short time, largely in consequence of windfalls, it appeared to be enjoying a substantial surplus, and important development works were put in hand. In 1921 revenue was £870,930, of which £547,419 was derived from mining receipts. Ordinary expenditure was £642,747, and extraordinary expenditure, mainly of a capital nature on irrigation and public works, was £192,160. The main cause of the subsequent difficulties of the territory has been the decline of the mining revenue; in 1932 ordinary revenue was reduced to £357,388, whereas ordinary expenditure was £602,964.

Since that year there has been a considerable recovery of revenue, to £669,140 in 1936, largely in consequence of increases of customs and mining receipts. From 1926 to 1937 the borrowings of the territory from the Union Government have amounted to £2,570,266, of which £1,183,272 has been for the purpose of meeting deficits on ordinary expenditure. Of the ordinary expenditure of £804,185 in 1936, as much as £183,253 was required to cover interest and redemption charges. During 1937 the Union Government agreed to place these loans and the interest charges upon them in a suspense account, and to permit the territory to postpone interest payments until the financial position improved. Education is a heavy expense with so scattered a European population, and received £146,692 in 1936. The total expenditure on natives, including administration, was £51,515. The total debt

¹ For the past history and for recent examinations of the problems involved see *Report of the Commission on the Financial and Economic Relations between the Union of South Africa and the Mandated Territory of South-West Africa*, U.G. 16, 1935, and *Report of South-West Africa Commission*, U.G. 26, 1936.

of the territory, including interest-bearing capital of the railways and the loans of the Union Government, was estimated by the South-West Africa Commission to be £3,671,900, equivalent to £131 per head of European population and £29 14s. per head of all population.

Southern Rhodesia, though it shares with the Union the advantage of a relatively prosperous mining industry, which contributed some £78,000 in licences, £186,000 in royalties, and £273,000 in income tax in 1936-7, shares with many of the African territories the difficulties arising from the administration of a large and low-populated area, with the added disadvantage that the standards of administration are dictated by the requirements of a white population. Of a total expenditure of £3,017,573 for the year 1936-7, the service of loans absorbed £471,050. Defence, including the cost of the British South Africa Police, required a further £325,467. The cost of European education was £332,321, and that of hospitals and dispensaries, mainly serving European needs, was £159,250. Native administration required £161,848, and the amount available for native development, which includes native education, was £78,338. The balancing of the budget was, until the recent rise in the price of gold, never easy. From its foundation until 1905, and from 1912 onwards, the Chartered Company's expenditure exceeded its revenue, and the Company estimated its accumulated deficits at £7,886,117 up to 1918. From 1921, however, the revenue has in general exceeded expenditure, and the deficits of occasional years have been small,¹ but the accumulated surplus was no more than £100,345 in March 1937. A public debt was first created in 1924 with the flotation of a loan of £3,000,000, mainly for the purpose of providing the colony's share of £2,000,000 in the compensation of £4,435,225 awarded to the Chartered Company. It has since been gradually increased to £10,898,263 at March 31, 1937. At that date it was about £192 per head of European population and about £8 10s. per head of all population.

Northern Rhodesia, in the years of the administration of the Chartered Company, suffered from a similar history of continuous deficits, which at the time of the negotiations between the Com-

¹ See S. H. Frankel, *op. cit.*, p. 233, Table 55.

pany and the Imperial Government were estimated to amount to £1,660,000.¹ When the Imperial Government became responsible for the finances, the régime of deficits continued, and grants-in-aid were for a time necessary, amounting in 1924-5 to £138,000 and in 1925-6 to £100,000. A new phase began with the development of mining in the years following 1928; customs revenue, for instance, which in 1926 was £100,000, rose to £321,000 in 1931. On the basis of the added revenues considerable expansions both of recurrent and capital expenditure were permitted. The recurrent expenditure, which in 1926 was £376,000, had risen in 1931 to £769,000. But in 1932 there was a serious setback; the end of the period of construction of the copper undertakings, in which large numbers of Europeans and natives had been employed, coincided with a collapse of the price of copper and a severe restriction of output. As a result, revenue fell to £600,000. An inquiry into the finances of the territory resulted in a general reduction of activities; the building of the new capital at Lusaka, which had recently been begun, had for a time to be considerably curtailed. There had been a surplus of £125,000 in 1930-1; despite retrenchment there was a deficit of £177,000 in 1932-3, and it was not until 1935 that a small surplus reappeared. Sir Alan Pim's investigation has made clear the dangers of embarking upon large recurrent expenditure on the basis of a temporary increase of revenue, and the importance of adequate reserve funds in a territory whose prosperity is so intimately connected with the fortunes of a single, and fluctuating, industry. The improvement in the earnings of the copper mines since 1934 has been the main source of the recovery of revenue, which was estimated to amount to £905,000 in 1937 and £1,361,000 in 1938. The receipts from mining are, however, much reduced by the fact that the companies working the copper are not registered in the territory. Instead of receiving the full local rate of tax, four shillings in the pound, the territory receives ordinarily only a half share of the United Kingdom tax. The Chartered Company retains the royalties in perpetuity, and these contribute only through taxation to revenue.² Thus, although mining is not taxed more lightly than

¹ See *Report*, op. cit., Colonial 145, 1938, p. 86 and Appendix IX, and S. H. Frankel, op. cit., p. 255, Table 61.

² See Chap. XXII, p. 1531.

elsewhere,¹ a relatively small share contributes to the finances of Northern Rhodesia. The public debt was first incurred in 1924. At the end of 1936 it amounted to £2,347,000. A further £262,000 had been lent by the Colonial Development Fund, of which £240,000 was re-lent to the Rhokana Corporation for the construction of an electrolytic refinery. The loan expenditure has been largely upon the new capital and other government buildings, which have together absorbed about £969,000, up to the end of 1936; roads and telegraphs have taken a further £585,000. Municipal services, such as gas and water supplies, mainly in the railway strip and copperbelt, have required £193,000. Some assistance in meeting the annual debt charges, which now amount to about £131,000, has been temporarily received from the Colonial Development Fund and the Beit Trustees. The foreign debt is now approximately £250 per head of the European population, and about £1 18s. per head of all population.

The budgetary problems of Nyasaland are those of a relatively poor territory, enjoying no revenue from mining, and burdened with high charges upon railway developments. The ordinary revenue of 1936 was estimated to be £395,350. There has been no such violent fluctuation of receipts as has been seen in territories more dependent on mining, and they have varied by less than £20,000 since 1928. To the total, customs and dues contribute about £150,000, and native tax about £125,000. The ordinary expenditure rose slowly from £396,799 in 1929 to £418,616 in 1934. There was a jump to £606,960 in the budget of 1936; this was mainly the result of an increase of debt charges from £61,175 to £230,832. The debt was incurred to enable the territory to take part in the operations for financing the railway extensions and the construction of the Zambesi Bridge, which will be described in detail in Chapter XXIII.² The loans are guaranteed by the Imperial Government, and until 1936 the interest payments were partially met from a grant of £500,000 from the Colonial Development Fund. Since the exhaustion of that sum the charge has fallen upon the Imperial Exchequer and required a grant-in-aid in 1937 of £161,271. A 'standard revenue'

¹ See *Report*, op. cit., Colonial 145, 1938, pp. 135-6.

² See below, p. 1577.

of £450,000 has been agreed between the British Treasury and the Nyasaland Government, so that any revenue below this total is within the disposition of the government of the territory, while half of any excess above it is applied to meeting the interest on the Treasury loans and the guarantee payments to the railway. Thus the territory will only be self-supporting if as the result of these developments taxable capacity is more than doubled. The public debt, including Exchequer loans, is a little over £5,000,000 and is equivalent to £3 2s. per head of all population.

Tanganyika suffered far more severely than did Nyasaland from the effects of the late depression. Revenue fell from £1,993,000 in 1929 to £1,522,000 in 1931, largely as a result of the decline of customs revenue; since 1933 there has been a rapid recovery. In 1936 there was a surplus of £176,593 after making special allowances to reserve funds, and there has been a further substantial surplus in 1937. The revenue in 1937 was £2,244,659. To this, customs contributed £727,000 and licences and taxes £876,000. Of the latter the native tax is the largest element, having in recent years brought in about £650,000. Like South-West Africa, Tanganyika received substantial grants-in-aid from the German Imperial budget before the War. In the years immediately following the War there were large deficits. A surplus first appeared in 1924, and they continued until 1929. From that year until 1935 there were continued deficits. Part of these has been met by borrowings from the British Treasury, to which the territory has a debt of £3,121,031. Of this a little over £2,000,000 was to enable the railway to make capital expenditure as well as to capitalize its arrears of interest. There is a further debt of £5,570,000, mainly for railway improvement, guaranteed by the Imperial Government under the Palestine and East Africa Loans Act of 1926, and a subsequent Act of 1932. On rather more than £1,000,000 of the Exchequer loans, no interest is being charged. This debt is equivalent to about £1 14s. per head of all population.

Of the expenditure in 1938, about £139,000 was required for debt charges, about £201,000 for provincial administration, and £257,000 for military, police, and prison services. About £157,000 was the estimated grant to the native administrations. The finances of the territory have until lately been embarrassed at

frequent intervals by the deficits of the railways. The separation of the railway accounts has now been completed, and during the years since 1935 the railways have earned enough to cover not only their recurrent expenditure but also their debt charges. They have not, however, been able to provide fully for depreciation or renewals, and the general revenues of the territory have been required to give assistance.

The recent financial history of Kenya, Sir Alan Pim suggested,¹ may be divided into three periods: 'the first of economy from 1922 to 1924, then of general expansion and lavish expenditure from 1925 to 1929, followed by steadily increasing depression and enforced economies from 1930 onwards'. The budget of Kenya differs from that of most other territories in that the interest charges on the railway are included in the expenditure, and are in an ordinary year offset by a reimbursement from the Kenya and Uganda Railway administration. Including these cross payments, the expenditure of 1922 was £1,909,051, of which £249,963 was required for interest payments; reimbursements covered £198,232 of this. Medical services received £145,332, agriculture £92,958, and education £56,118. The total revenue, £1,649,032, was derived to the extent of £506,414 from the native hut and poll tax, and of £387,530 from customs. By 1930 expenditure had risen to £3,114,912. This included £814,683 for interest payments, £236,934 for medical services, £160,804 for agriculture, and £180,734 for education. The total recurrent expenditure was reduced during the years 1931-3 to about £90,000 below the maximum of 1930. In 1934 and subsequent years expenditure has again risen above the level of that year. The expenditure upon agriculture has, however, been curtailed by some £35,000 and that on medical services by about £40,000. Interest charges, on the other hand, have risen, and in the budget of 1937 were estimated to require £1,054,502. During the depression years ordinary revenue declined from a maximum of £3,333,742 in 1929 to a minimum of £3,006,611 in 1932, mainly as a result of a decline in customs revenue from £949,725 to £597,262. The result was a series of deficits which, if non-recurrent items of income and ex-

¹ *Report of the Commission on the Financial Position and System of Taxation of Kenya*, Colonial 116, 1936, p. 18.

penditure are included, amounted to £171,331 in 1930, £197,274 in 1931, and smaller amounts in the two following years. The estimated revenue for 1937 was £3,436,322; to this it was expected that customs and excise would contribute £740,000, native hut and poll taxes £540,000, the income tax £83,500, the non-native poll tax £52,000, and reimbursements (mainly from the railway) £1,051,824.

At the end of 1936 the public debt of the territory amounted to £17,580,600. Of this, £5,000,000 was borrowed in 1921 at a rate of 6 per cent. and at an issued price of £95. A further £5,000,000 was borrowed in 1927 at 5 per cent. The interest and sinking-fund charges are thus for the time being very heavy. There is a further contingent liability to the British Treasury in respect of the £5,502,592 which represents the cost, borne by the British Government, of the original construction of the Kenya-Uganda Railway. While it has been recognized by the Colonial Office as a liability of Kenya, no payment has ever been made; down to 1912 the colony required a grant-in-aid, and an increase of that sufficient to make possible the payment was considered an unnecessary complication. When the grant subsequently became unnecessary the financial position of the territory made it difficult for the payments to be undertaken. Sir Alan Pim recommended in 1936 that the colony should be relieved of the burden. If this debt be omitted, the remainder is equivalent to about £977 per head of European population or £5 14s. per head of all population.

Uganda, like Kenya, for some time required a grant-in-aid, progressively reduced from £204,000 in 1900 to £96,000 in 1910 and finally extinguished in 1914. Expenditure, which before the War was about £250,000 annually, had increased to over £1,000,000 by 1925 and to £1,643,293 by 1930.¹ It was somewhat curtailed during the depression, largely by reduction of public works, but had increased again to £1,624,073 in 1936. This figure included £137,598 for debt charges. The public debt is no more than £2,235,600, equivalent to about 12s. 7d. per head of all population. A little under half of the interest charges are reimbursed by the railway administration. In consequence of these relatively low debt charges there is a large surplus available in

¹ See Uganda Protectorate, *Annual Report by the Treasurer for 1936*, p. 13.

ordinary years above the essential needs of administration and the other fixed obligations of the government for expenditure upon public works and other forms of economic and social development.

Thus the 1937 budget provided for £2,011,417 of expenditure, of which £1,489,959 was recurrent. The remainder was extraordinary and other special non-recurrent expenditure, mainly upon public works and equipment of a capital nature. Of a total revenue of £1,712,940 in 1936, £496,709 came from customs and excise. About £560,000 came from the native poll tax, and about £31,000 from the non-native poll tax. A tax on all cotton grown in the territory yielded slightly under £129,000. Of the expenditure of the same year, the provincial administration required approximately £115,000, pensions £108,000, native affairs £157,000, medical services £164,000, and education £80,000. The reserves and accumulated surplus are considerably greater in relation to annual expenditure than those of most other territories. They amounted at the end of 1936 to £1,695,902.

The financial problems of Nigeria have been dominated by two factors, the wide fluctuations of revenue, and the deficits of the railway administration. The revenue, which was £6,305,000 in 1927, had fallen to £4,858,000 in 1931, and rose again to £6,260,000 in 1936. Customs revenue, which was £3,541,000 in 1927, fell to £2,077,000 in 1931 and was £3,624,000 in 1936. This variation reflects the wide changes in the values of the produce of Nigeria, more particularly those of tin, cocoa, and palm products. The railway has been from the first an instrument of colonial development, and the deficits have been regarded as a necessary consequence. Since the traffic has been dependent upon the volume of agricultural exports and upon the imports which could be purchased with them, the receipts have fluctuated greatly. Until 1927 the gross revenue and expenditure of the railway appeared in the general budget. From that year only the railway surplus or deficit was included. Since 1936 the railway finances have been more completely separated. The general budget has been made responsible for an annual contribution to the railway of £214,000, representing the interest charges on the Enugu-Kafanchan branch, which was built mainly for development purposes,¹ and the capital

¹ See Chap. XXIII, p. 1585.

investments in the railway made from government balances have been written down and the rate of interest reduced. The railway has been made responsible for its own interest charges, for a sufficient payment to a renewals fund, and for the building up of a reserve. It is hoped that by these means the railway administration will have a more clearly defined financial task, and that the annual obligations of the government will be more constant and more easily foreseen.

From 1927 to 1933 Nigeria suffered a continuous series of deficits. During the following years, under the governorship of Sir Donald Cameron, the finances were thoroughly overhauled and a small surplus appeared in 1934, insufficient, however, to meet the necessary payments to the railway renewals fund. In subsequent years there have been increasing surpluses. To the total revenue of 1936 mentioned above, the main contribution apart from customs was that from direct taxes, which yielded £851,800, of which only £13,887 was the product of the non-native income tax. Of the total expenditure of the same year, £288,212 went as special payments to the railway renewals fund and the supplementary sinking funds. The public debt charges required £944,087 in addition to the sum of £761,092 which was the interest charges of the railways. The total outstanding debt of the territory in 1937 was £24,764,599, equal to about £1 4s. 6d. per head of population. Of other expenditure, provincial administration required £419,553, medical services received £387,600, agriculture £111,257, education £247,795, and public works £780,604. It must be remembered that the expenditure from native treasuries is not included in these figures. Their expenditure amounted to a further £1,478,456 in that year. The accumulated surplus at the end of the year 1936-7 was £2,819,575. There were holdings of £909,996 of cash and £3,837,335 of investments against this surplus and the various outstanding liabilities of the territory.

The Gold Coast is like Nigeria in suffering from large variations of revenue. It fell from £4,112,000 in 1927 to a minimum in 1931 of £2,284,000, and, as in Nigeria, the principal cause was a decline of customs revenue from £2,410,000 to £1,474,000, largely accounted for by the gradual abolition of gin imports after the

imposition of the Liquor Traffic Ordinance. The revenue from spirits and other liquor fell from £1,509,901 in 1927 to £193,248 in 1934. The buoyant revenues of the years 1919-27 had led the government to a cautious but steady increase of expenditure. By the budget of 1928 recurrent expenditure had risen to £2,552,809, amply covered by an estimated revenue of £3,422,476. An estimated extraordinary expenditure of £602,983 was calculated to leave a surplus of £266,684. The reserves and accumulated balances were so strong as to suggest confidence in a steady advance of the territory and an increase of expenditure upon development services. The subsequent years, however, showed such reductions of revenue that first extraordinary expenditure, and later the recurrent expenditure, had to be severely curtailed, and between 1929 and 1932 the European establishment of the territory had to be reduced from 1,281 to 437. Revenue began to increase in 1932, and from 1933 there has been a small surplus, which has made possible an increased expenditure upon public works, and a restoration of some of the more essential services that had been retrenched during the depression. The 1936 estimates provided for recurrent expenditure about £127,000 greater than that of 1933 and for extraordinary expenditure £491,000 greater. Increased payments have been made to the railway renewals fund and to reserve funds. The anticipated excess of assets over liabilities at the end of the year 1936-7 was £855,765. The public debt of the colony was £11,435,000, requiring interest and sinking-fund payments of £559,719. Of this, £104,148 is borne by the general budget and the remainder by the railways and by Takoradi harbour. The debt is equivalent to about £3 5s. per head of all population. Of the budgeted expenditure of 1936-7 the political administration required £123,630, and pensions of all kinds £243,190. The Medical Department received £320,288, Education £184,546, and Agriculture and Animal Health £101,966. The chief source of revenue was customs duties, estimated to yield £2,227,790 out of a total of £2,924,515. To this total, export duties on cocoa, gold, and diamonds were expected to contribute £274,000, £200,000, and £42,000 respectively. A profit tax yields about £30,000, royalties about £70,000, and the remainder comes from a wide variety of fees and licences.

Sierra Leone has encountered difficulties during the depression very similar to those of the two larger West African territories. Ordinary revenue fell from £771,657 in 1928 to £559,907 in 1934. Since 1935 there has been a substantial surplus, and the 1937 budget provided for a revenue of £785,414, for a recurrent expenditure of £672,793, and an extraordinary expenditure of £74,985. The main source of revenue is customs, estimated to produce £420,000, of which £82,000 is from export duties on palm kernels and kola. The native house tax produces £78,500, profits tax £85,000, and the non-native poll tax £5,100. The provincial administration required £62,558 and pensions £61,710. Education received £41,714, medical services £56,890, and agriculture £17,845. Public works received £74,038 for recurrent and £35,972 for extraordinary purposes. The loss incurred by the railway and a subsidy to it absorbed £61,794. Public debt charges required £100,736, of which £43,085 was borne by the general budget and the remainder by the railway. The total debt is equivalent to some £1,718,259, about 19s. 5d. per head of all population. The accumulated surplus at the end of 1937 was expected to amount to £246,792.

It is convenient at this point to summarize the assistance given by Great Britain to its African dependencies. This assistance takes a variety of forms. In the first place help is given to individual territories, sometimes by grants-in-aid of local revenues, sometimes by loans-in-aid, sometimes by interest-free loans. Less direct and less easily measurable help is given by guarantees of loans, imposing a contingent liability upon the British Exchequer. In addition to these forms of direct assistance, borne chiefly upon the Colonial Office Vote, but in the case of the South African High Commission Territories upon the Dominions Office Vote, grants and loans are made indirectly through the Colonial Development Fund, which itself receives an annual grant, which amounted in 1938 to £650,000.¹ In the second place help of a general nature is given to the colonial territories in several ways. The costs of the squadrons of the Royal Air Force serving in Africa are borne by the imperial budget, though their presence often contributes to

¹ Under the Colonial Development Act, 1929, such sums may be paid to the Fund as Parliament may decide, but not exceeding one million pounds in any year.

local as well as general security. The military defence of African territories, on the other hand, is paid for out of local revenues, though in some cases it may be said to serve imperial as well as local ends; thus it is sometimes claimed that the military expenditure upon the northern boundary of Kenya is not solely in the interest of that colony.

Apart from these imponderable elements, there are grants to certain institutions of common interest to all or many African territories. Reference is made in Chapter XXIV¹ to the Imperial Bureaux of Agriculture and institutions such as the Medical Research Council, which take a direct part in assisting research in the African colonies; the latter also benefit from the regular grants of £6,000 to the Amani Agricultural Research Station, and £16,000 to the Imperial College of Tropical Agriculture, Trinidad. They share in the advantages of the marketing research conducted by the Colonial Empire Marketing Board with an annual grant of £40,000. From time to time special grants-in-aid are also made for purposes of imperial as well as local concern. Thus a grant of £70,000 to Kenya was approved in 1938 mainly to provide assistance for refugees from the Abyssinian war.

In the early years help to individual territories largely took the form of grants-in-aid. Since the War the practice of giving loans rather than grants was extended, in order that any territory whose financial position improved might be under the obligation to pay off some part of the deficits involved in its past administration. There has more recently been a tendency to revert to the practice of making grants-in-aid. The accumulation beyond a certain point of debts which have no relation to the financial capacities of the territory, and which from lack of means to meet their service were necessarily interest free, was rightly considered to diminish the financial responsibility of the administrations. The treatment of the accumulated indebtedness of the past has also come under consideration. These changes more particularly concern Somaliland, Nyasaland, Bechuanaland, and Swaziland. In the case of Bechuanaland and Swaziland loans-in-aid amounting to £57,000 and £44,500 respectively in 1937 and £50,000 and £53,500 in 1938 have been approved. But it has been indicated that the review of

¹ See below, pp. 1617 ff.

unrepaid advances mentioned above may involve a change from loan to grant.

The financial position of Nyasaland has lately been reviewed in the light of the complications arising from the financing of the railways and the Zambesi Bridge. For some time the territory had been assisted by loans-in-aid, but since 1936 it has received grants-in-aid to meet the interest and sinking-fund payments on its guaranteed loans. The British estimates for 1938 make provision for a grant-in-aid of £150,000 for this purpose, and for a loan of £56,000 to meet its railway guarantee.

The loans-in-aid made in the past in some cases carry interest. Those of Nyasaland, for example, carry a nominal interest of 5 per cent. in addition to a sinking fund. But owing to the financial state of the territory, the sinking fund has been from time to time suspended, and the interest payments have accumulated instead. The loans-in-aid given to Swaziland and Bechuanaland are repayable on terms prescribed by the British Treasury. In effect neither interest nor sinking fund is met on the greater part of the borrowings. In addition Tanganyika has a debt to the Exchequer of £1,075,508, borrowed in the years immediately following 1921. On this no interest has hitherto been paid, but the future terms of the loan are at present under discussion. Finally there is the debt of £5,502,592 for the original construction of the Kenya-Uganda Railway, also now under discussion.¹

The total assistance approved from the Colonial Development Fund during the first nine years of its existence has been £7,284,682. Of this, individual African territories have received £4,040,201, of which £2,401,575 was given in grants and £1,638,626 in loans. Africa thus received about 56 per cent. of all grants and about 54 per cent. of all loans. In addition grants of £6,500 have been made for general African purposes, and grants amounting to £108,765 have been made for general colonial purposes, mainly for agricultural, veterinary, and forestry scholarships, and for assistance to central research stations; it may be taken that approximately £60,000 of services has been derived by Africa from this source. Thus the average assistance to African territories from the Colonial Development Fund in grants, as distinct

¹ See Chap. XXIII, p. 1582.

from loans, during these nine years has been approximately £275,000 a year.

From these figures a very rough estimate may be made of the current assistance given to the British African dependencies. It must be emphasized, first that the resulting figures can be only an approximation, sufficiently accurate to indicate the order of magnitude, but not to be regarded as unassailable in detail, secondly that the calculation excludes all the costs of defence and all contingent liabilities in respect of guaranteed loans. If the payments to Somaliland, Bechuanaland, Swaziland, and Nyasaland are treated as grants rather than loans their total is £277,000. The total grant to Amani, and a share of the grants to Trinidad and to the Colonial Empire Marketing Board would amount to approximately £37,000. If interest were charged at 4 per cent. on about £1,700,000 of outstanding Exchequer loans (excluding that for the Kenya-Uganda Railway) it would amount to £68,000. Including the average annual grant from the Colonial Development Fund, these make a total of £657,000.

The character of the contributions made by African colonies to imperial institutions, or to similar objects, may be illustrated by the case of Tanganyika. In 1936 there was a total expenditure upon subventions, both imperial and local, of £24,608. Of this £6,000 was the contribution to the Amani Research Station, £3,069 a grant to the Sisal Tax Board, £1,300 Tanganyika's share of the East African meteorological service, £769 that of the East African Trade and Information Office, and £1,139 that of the Governors' Conference secretariat. £7,000 was given in subsidy to the air mail service. In addition to these larger contributions there were a number of small contributions of less than £1,000 each to various research institutions and educational schemes. Thus there were grants of £709 to the Inter-Territorial Language Committee, of £512 to the Agricultural Scholarship Scheme, of £500 to the Bantu Kinema Experiment and the Imperial Institute of Entomology, and of £250 to the Imperial Mycological Institute, the Imperial Forestry Institute, the Imperial College of Tropical Agriculture, Trinidad, and the Colonial Agricultural Service Fund.

In approaching the similar questions which arise in regard to

the French and Belgian colonies there is one initial difficulty. The British system of compiling public accounts, and the tradition which constrains administrations to convey the fullest amount of information to the public on financial as well as other matters, render the examination of the British colonial budgets far easier than that of other colonies.¹ The examination of the finances of the French colonies is made more difficult on account of the inter-relations of the metropolitan and colonial budgets, and in the case of French West Africa in particular by the existence of a federation of territories, each of which possesses also a local budget. Certain branches of expenditure, which are more particularly concerned with imperial welfare and policy, are centralized in the metropolitan budget of France. A second group of expenditures are financed from the federal budget of French West Africa. A third group are financed from the local budget of any one of the constituent territories in the federation, for instance Senegal or the French Sudan. The estimated expenditure from the metropolitan budget upon all French colonies, including the cost of central administration, was in 1937 approximately 780,000,000 francs, of which military expenditure accounted for about 605,000,000 francs. Towards this the colonies were estimated to make contributions amounting in total to about 54,000,000 francs, mainly for military services. The largest contribution was that of Indo-China; French West Africa was estimated to contribute about 7,700,000 francs, and French Equatorial Africa about 640,000 francs. From the metropolitan budget there are temporary grants made to various local budgets and railway administrations. Thus the estimates for 1937 included a figure of 76,000,000 francs to cover extraordinary grants and repayable advances to the general budget of French Equatorial Africa.

The federal receipts in French West Africa, apart from loans and subventions, were estimated in 1937 at about 184,000,000 francs. The main, and in fact the only large source of ordinary revenue was import and export duties. Of the ordinary expenditure about 74,000,000 francs was required for debt services, about

¹ One effect of the mandatory system (see Chap. VI, p. 216) is that the French mandated territories publish a much clearer statement of accounts than the neighbouring colonies.

11,000,000 francs for contributions to the metropolitan revenues and to certain other services jointly performed by the African colonies, and 16,000,000 francs for subventions to the local budgets of the federated territories. The remainder of the budget was required to provide for the central administration itself, as well as for central expenditure upon economic and social development, both initial and recurring. In addition to the general federal budget there are in French West Africa three supplementary budgets of the federation, one for the railways, one for the administrative district of Dakar and one for the port. The railways, which during some of the depression years had been working at a deficit, were estimated in 1937 to cover their costs. A separate renewals account, deriving its income in part from profits, in part from grants from the general budget, showed a balance of 154,000,000 francs.

The budgets of the colonies forming the federation bear the main cost of local administrative personnel and equipment, as well as of purely local social services and public works. Thus the local budget of Senegal had estimated receipts in 1937 of some 102,000,000 francs; of the total expenditure, about 21,000,000 francs was required for salaries of the administrative and financial services; about 27,000,000 francs was available for expenditure on state-owned industrial enterprises, and for economic and social development. The total of the estimated ordinary expenditure for 1937 from all local budgets in French West Africa was approximately 380,000,000 francs; the extraordinary expenditure was estimated to amount to a further 28,000,000 francs.

The financial position of all French colonies formed a matter of concern to the metropolitan government during the years of depression following 1929. Under the administration of M. Laval, drastic deflation of colonial budgets was undertaken, whereby annual expenditure was to be reduced in total from 3,642,000,000 francs in 1930 to 2,476,000,000 francs in 1934. The ordinary budgets of the West African group of territories were to suffer a reduction from 797,000,000 francs to 575,000,000 francs. The bulk of these economies were in fact achieved, and expenditure in 1934 was reduced to 603,000,000 francs; the deficit, which in 1931 had been as much as 86,000,000 francs, had by 1933 been turned

into a small surplus, which by 1935 had been increased to 60,000,000 francs. The budgets of 1936 and 1937 have thus shown an increase of expenditure, which is again not greatly below the level of 1930.

In addition to the budget of ordinary receipts and expenditure, there is a federal loan budget for French West Africa, from which are financed the major capital developments of the federation. These include the Niger irrigation schemes,¹ extensions of the railway and road systems, harbour works, river and coastal navigation improvements, as well as capital expenditure upon health and education services. An act of 1931, as subsequently amended in 1934 and 1936, authorized capital expenditure which will amount in total to 1,837,000,000 francs. Of this 628,000,000 francs is for railways, 300,000,000 francs for Niger irrigation, and 227,000,000 francs for industrial and agricultural development. The total expenditure from the loan account to the end of 1937 was estimated to be 781,000,000 francs; that on the Niger irrigation was expected to amount to 159,000,000 francs, on railways to 226,000,000 francs, and on ports and rivers to 227,000,000 francs. The expenditure on industrial and agricultural development had not exceeded 43,000,000 francs, but since it includes provision for improvements in connexion with the Niger schemes, it is doubtless only temporarily low. The service of the loans formed a heavy charge in the depression years, but is now only 19 per cent. of the total expenditure. The loans are at a nominal rate of interest of 5½ per cent., and when allowance is made for the terms of issue and repayment, and for amortization, the effective rate becomes approximately 6·21 per cent. Time alone can show whether African developments can support so high a rate;² the returns realized by the Niger irrigation scheme will, in particular, have an important bearing on the finances of the federation.

The financial position of French Equatorial Africa has always been more difficult. Unlike French West Africa, it is since 1934 no longer a federation, and there is now a single local budget, with an additional special budget for the Congo Océan-Pointe Noire Railway.³ Despite every attempt to achieve economy, a balance

¹ See Chap. XV, p. 1049.

² The average rate of interest on the public debt of the Union was 3·96 per cent. in 1935; the average rate for the British African colonies was 4·72 per cent. See S. H. Frankel, *op. cit.*, chap. v, p. 178.

³ See Chap. XXIII, p. 1589.

was only obtained in the estimates of 1937 through a subvention of 79,000,000 francs, almost equal to the entire debt charges of the territory. Ordinary receipts, including the subvention, were estimated to amount to 196,000,000 francs. The railway receipts were similarly estimated to cover only the bare costs of operation, making no contribution to interest charges or a renewals fund. Of a total ordinary expenditure, including debt service, of 198,000,000 francs, about 48,000,000 francs represented the cost of the administrative and financial services, about 12,000,000 francs was provided for public works, and 19,000,000 francs for social services, chiefly medical and educational. The main sources of local income are the capitation tax, yielding about 39,000,000 francs, import and export duties, yielding 48,000,000 francs, and forests, yielding about 5,000,000 francs.

As in other French territories, there is a separate loan budget. The original schemes for capital development have been curtailed in view of doubts as to the wisdom of increasing the debts of the territory. The schemes approved for loan expenditure involve a capital cost of 1,513,000,000 francs, of which 1,170,000,000 francs was for the Pointe Noire Railway, and 177,000,000 francs for the harbour works. It was expected that the entire work would be completed and the loan expenditure exhausted before the end of 1937. The nominal and effective rates of interest are the same as those for French West Africa. It will be seen that the service of the loans is estimated at just over 80,000,000 francs, or 40 per cent. of the ordinary expenditure.

The financial systems of the other French possessions and of the two French mandates in the Cameroons and Togoland follow the general lines that have been indicated above. Of the ordinary revenues of the mandated territory of the Cameroons, amounting in 1935 to approximately 63,000,000 francs, 28,000,000 francs was from personal taxes (25,000,000 francs of this coming from the native tax), and 22,000,000 francs from customs duties. The amounts expended from loan funds are relatively small; the authorized loan was 57,000,000 francs, of which 44,100,000 had been issued up to 1937. The service of the loan amounts to 5 per cent. of the annual expenditure. Of the ordinary revenue of the Togoland mandated territory, totalling 26,000,000 francs, about

¹ Excepting the Cameroons, for which the figures are for actual expenditure, 1935.

² The analysis for French West Africa is of the total of both the general budget of the federation, and the local budgets of the individual territories. The budgets of the railways and of the Port of Dakar are omitted. Subventions amounting to 16,100,000 francs from the general to the local budgets are deducted. The 'budget spécial des grands travaux, etc., sur fonds d'emprunt' is not included. From that budget the following additional expenditure was estimated to be made during the year: (1) grands travaux, 191,000,000 fr., (2) dépenses sanitaires, 17,000,000 fr., (3) divers, 6,000,000 fr.

³ Excluding the railway budget and the 'budget spécial sur fonds d'emprunt'.

⁴ This includes expenditure on the central judiciary, inspectorates of public works, health, and education, &c.

⁵ This expenditure is mainly for the personnel of the financial administrations.

⁶ The public works are being financed from the loan budget.

5,000,000 francs was received from personal taxes, about 9,000,000 from customs, and about 2,000,000 from a turn-over tax. As compared with the Cameroons the loan charge is relatively heavy, 73,000,000 francs having been borrowed, and the debt charges for 1934-5 amounting to 16.6 per cent.¹ of the annual expenditure.

An analysis of the estimated expenditure of the French African colonies is given in Table XIV (p. 1453) in a form sufficiently comparable to that for the British territories to be of interest.

The dominating factor in the budget of the Belgian Congo is the heavy load of debt charges. Of a total expenditure of 689,000,000 francs in 1934 as much as 316,000,000 francs was required for the service of the public debt. It was pointed out by the Governor-General, M. Ryckmans,² that the debt charges upon this territory, with a population of less than 10,000,000, were considerably greater than those of Nigeria with a population double the size. The character of the public debt, however, differs in one respect from that of the British territories; a considerable part represents the government investment in mining and other development companies, or advances to assist agricultural development.³ Thus, in the year mentioned above (1934), the colony derived some 46,000,000 francs from its share-holdings in companies and from interest on loans. By the end of 1936 the public debt of the Congo amounted in total to approximately 6,654,000,000 francs. In recent years the colony has found it difficult to balance its budget without assistance. In 1934 the total expenditure of about 689,000,000 francs was met only to the extent of 357,000,000 francs from ordinary sources; a subvention of 165,000,000 francs received from the metropolitan government still left a deficit of a further 167,000,000 francs. The grant of subventions commenced in the previous year, 1933, and was made partly in recognition of the substantial holding of the Belgian Government in the mining and other development companies of the Congo colony.⁴

Since 1934 the situation has improved and the yield of taxation

¹ *The Colonial Problem*, Royal Institute of International Affairs, 1937, p. 339.

² See *Annuaire de documentation coloniale comparée*, 1936, vol. i, p. 11.

³ From 1909 to 1932 a sum of £765,000 was advanced out of loan funds for agricultural development. See S. H. Frankel, *op. cit.*, p. 58, note (1).

⁴ For an analysis of the relations of the government with these companies see S. H. Frankel, *op. cit.*, chap. v, pp. 289 ff.

has increased. The devaluation of the currency in March 1935 brought about a new relation of internal to external prices, and a rapid increase of prosperity to the territory, reflected in rising prices for all raw materials sold in world markets. To allow the budget to benefit by some part of this gain, export duties, mostly of 3 per cent. *ad valorem*, were imposed upon various vegetable and mineral exports; at the same time import duties were reduced in order to prevent the increased costs of imported goods from unduly raising prices and depressing standards of living. Apart from copper, sales of which were limited by international agreement, almost every export was substantially increased. The subvention of 165,000,000 francs was, however, continued for 1935; it was reduced to 155,000,000 francs in 1936. The estimated receipts for 1938 have risen to 717,000,000 francs, and with an estimated expenditure of 767,000,000 francs, a subvention of 50,000,000 francs will, it is hoped, serve to balance the budget. It must, of course, be recognized that in the case of the Congo a deficit is due not merely to uncovered expenditure on the ordinary services of the administration, but reflects also the fact that it has been necessary for the state to implement its guarantee in regard to the numerous companies, railway, mining, and others, in which it has a financial interest. It would, for instance, appear that up to 1934 it had made itself responsible in the way of guarantees, dividends, and the like for an amount exceeding 2,600,000,000 francs, and the payments under these guarantees amounted in that year to 110,000,000 francs.

Of the ordinary budget receipts of 1935, amounting to 424,000,000 francs, about 124,000,000 francs came from customs duties. The other main sources of revenue, apart from the subsidy and the income from shares and loans, were the native tax, yielding 83,000,000 francs, and the tax on company profits and professional incomes, yielding 53,000,000 francs.

The expenditures of the Belgian Congo and of the mandated territory of Ruanda-Urundi are analysed under broad headings in the table on page 1456.

The Portuguese territories do not differ greatly from others in their use of the different forms of taxation open to African territories. In Angola it was expected that 48,000,000 of the estimated

revenue of 184,000,000 angolares in 1937 would be received from import and export duties and other indirect taxation, about 39,000,000 from the native tax, and 15,000,000 from state enterprises. In Moçambique, of about \$241,000,000 of ordinary revenue, about \$90,000,000 was the estimated proceeds of the native tax, about \$56,000,000 that of customs and other indirect

taxation, and about \$25,000,000 receipts on account of emigrant native workers. Both the government area and the Moçambique Company area draw most of their receipts from their transit traffic; the imports for local consumption and the domestic exports of the territory are small compared with the transit trade. Both the western and eastern colonies differ, however, from other territories in that public debt charges form in neither case an appreciable element in expenditure. In Angola they amount to about 9 per cent. of expenditure, and in Moçambique to less than $\frac{1}{4}$ per cent., even when capital expenditure is excluded.

Attempts have been made in some territories to assess the respective contributions to revenue and the benefits from expenditure of the different racial communities. Such an analysis is surrounded by pitfalls. The ultimate incidence of taxation, and in particular of indirect taxation, can seldom be deduced from the forms in which it is imposed. Nor can the benefits be assessed by tracing the identity of the first recipient. A subsidy to European

farmers, for example, may exert part of its effects in making possible the maintenance of a higher level of native employment and of native wages, and a greater facility for the payment of native taxation, than would have existed without it. As has been shown, the legislation of the Union embodies the principle that expenditure on native services should be met from native taxation.¹ The task of assessing the contributions of natives and the benefits received by them formed one of the terms of reference of the South African Native Economic Commission (1930-2). The commission realized that any such investigation involved so many arbitrary and contentious hypotheses that no satisfactory result could be attained. While refusing to commit themselves to any definite conclusions, they suggested that in 1929-30 the natives' contribution to revenues, amounting to something over £3,000,000, fell short of their share of expenditure by about £1,000,000. But, as the Commission remarked, 'it is not usual . . . to consider taxation and public expenditure from the point of view of any one class of persons; the expenditure which the State considers necessary is regarded as a charge against the whole community, and it is the task of the government to distribute this equitably among the various classes of persons which constitute the State'. The total expenditure chargeable against natives was estimated for 1929-30 at £4,184,700. The fact that only some £1,084,700 represented the expenditure on purely native services, and that the remainder was the calculated native share of the costs of general administration, will show how wide is the range of assumption which any such calculation must involve. It is of interest to note that the expenditure per head on the purely native services was 2s. 11d., of which 1s. 10d. per head was spent on general native education.

A somewhat similar investigation formed a part of the inquiry made by Lord Moyne in 1932 into the finances of Kenya. After encountering difficulties similar to those of the Native Economic Commission, Lord Moyne separated contributions and services into those which were, and were not, divisible upon a community basis. He found that the European community contributed about £665,781, and received in purely European services about £171,247, the Asiatic community contributed £385,658 and

¹ See Chap. X, p. 554. See also Chap. XVIII, p. 1213.

received £46,080,¹ and natives contributed £791,100 and received £331,956. Thus their respective contributions to the general and indivisible body of administrative expenditure might be viewed as £494,534, £339,578, and £459,144. How far, in the light of their relative numbers, this was an equitable division, he found no precise means to determine.² But he formed the opinion that in the development of the undivided services in Kenya, the prevailing bias (as to the merits of which he expressed no conclusions) had been toward the convenience of a civilization in which the native so far shares little of the direct advantages. The native could not in his present circumstances fairly be expected to make heavier contributions, and if further revenue had to be raised it ought to be from the non-native.³

In other territories no precisely similar analysis is available, nor would it, indeed, have any great significance in regard to territories, such as those on the West Coast of Africa, where the resident European population is comparatively small, or is represented mainly in the cadres of the administration. But it is of interest to note the extent to which different territories are dependent on forms of taxation which fall predominantly upon one community rather than another. The taxation which first calls for consideration is the direct native tax, the character of which was described in Chapter X. In some of the more purely native territories, such as Basutoland, Uganda, Tanganyika or Nyasaland, where direct native taxes⁴ contributed in 1935 a proportion of 48·0, 37·9, 34·5, and 32·1 per cent. respectively of the total revenue, they have formed an important source of income. In the territories with a larger European element, Kenya, Northern Rhodesia, and Southern Rhodesia, where they provided 25·0, 17·1, and 14·4 per cent. respectively, their contribution was less important, but was nevertheless substantial. The British West African territories have relied largely upon other forms of taxation; the direct native tax does not exist in the Gold Coast, and yielded only 11·8 per cent. of total revenue in Sierra Leone and 14·8 per cent. in Nigeria, ex-

¹ See Chap. VIII, p. 339 for Lord Moyne's figures regarding the contribution of the Asiatic community.

² At the time there were 17,285 Europeans; 56,903 Asiatics; and 2,950,000 natives.

³ *Report on Certain Questions in Kenya*, Cmd. 4093, 1932, p. 27.

⁴ The figure used in this calculation includes all classes of direct native tax.

cluding in the last-named the sums going to native administrations. The British Cameroons came nearer to the level of the East African territories, deriving 29.1 per cent. of its revenue from native tax. In non-British territories the contribution is similar. In 1933 in the French Cameroons it was 50 per cent., in French West Africa 28.7 per cent., in the Belgian Congo 25 per cent., and in Ruanda-Urundi 35.8 per cent.

The yield of non-native direct taxation is insignificant except in the Union, where the taxation of European incomes has naturally formed an important source of revenue, yielding in 1935 as much as 32.6 per cent. of the whole, and in the Rhodesias, where the taxation of mining companies contributes substantially to revenue.¹ The contribution of all items of direct taxation of non-natives was 21.1 per cent. of the whole in Northern Rhodesia and 20.8 per cent. in Southern Rhodesia. In no other territory, apart from Swaziland, where it contributed 6.3 per cent., did non-native direct taxation yield more than 6 per cent. of the total revenue. In Kenya it was 5.9 per cent., and in Nyasaland 4.8 per cent., including in each case the levy on official salaries; in Tanganyika it was 4.7 per cent., and in the Belgian Congo in 1934 it was 5.7 per cent., excluding the *impôts sur les revenus professionnels*, which with *revenus repartis par les sociétés par action* contributed 11.8 per cent. of current revenue.

The main dependence in most territories has been upon customs and excise duties. In British West Africa they have been the predominant source of revenue. In the Gold Coast in 1935 they contributed 79.4 per cent. of the whole, of which 17.6 per cent. came from export duties, mainly upon cocoa, gold, and diamonds. In Nigeria they contributed 54.3 per cent., and in Sierra Leone 66.9 per cent. In the richer, more mineralized, or more settled territories, the part played by customs and excise revenue has been somewhat less. In Northern Rhodesia it provided 38.7 per cent., in Southern Rhodesia 31.3 per cent., and in the Union 33.6 per cent. of total revenue, excluding as before that of the self-balancing departments.

Reliance on customs duties as a source of revenue normally produces the same effect as a régime of protection. Apart, how-

¹ See above, p. 1437.

ever, from the Union, protection for local industries forms no part of the economic policy of the governments in Africa, and the merits of the customs system—apart from the production of revenue—must be sought in other directions. The forms of native taxation are, in almost every case, insufficiently graduated as between richer and poorer individuals and areas, and need to be supplemented by a scheme of taxes which will fall upon those possessing exceptional capacity to pay;¹ the purchase of imports is one important evidence of such capacity. In the case of the European agricultural community there is a similar advantage. To measure agricultural profit in the face of changing prices, and of the capital improvements which form a large part of the activity of settlers in a new country, is a task which would require both more willing collaboration than the taxpayer will ordinarily concede, and a staff of officials of capacity and experience, which few such territories can afford. Somewhat similar difficulties in computing profits arise in the case of the Asiatic trading communities, and the possibilities of evasion make difficult any great dependence upon direct taxation. Customs duties suffer, however, from one marked drawback. In most African territories imports of consumption goods reflect the surplus at any moment over and above the necessary expenditure upon foodstuffs, which are provided mainly from local sources. This surplus fluctuates violently as between boom and depression. Moreover, most of those territories which have seen industrial development have derived a part of their customs revenue from the taxation of imports of constructional goods, both in the form of machinery and in that of the raw materials or tools for building. Thus the customs revenue has oscillated according to the rate of foreign investment in the territory. During a period of construction, owing to the larger numbers of Europeans present for that purpose, there will also be a greater importation of consumption goods. In Northern Rhodesia, for example, during the period of construction of the copper mines in 1931-2, the yield of customs and excise was £342,017. In 1932-3 it had fallen to £177,671.

It will be apparent that a period of active foreign investment may thus delude a government into incurring loans, or permitting

¹ See Chap. X, pp. 594 ff.

a growth of expenditure, which its revenues cannot support when the period of capital investment is completed. This danger is the greater for a further reason. If foreign loans are employed, as they have been in some cases, for the erection of a new capital, and for public buildings or schools which, however desirable otherwise, do not contribute directly to the expansion of productivity as regards exportable goods, the payment of interest will create its own problem. It must involve a net addition to the export surplus of the territory, derived either from an increase of exports or a reduction of imports. The necessary increase of taxation will impose an immediate curtailment of individual expenditure upon imports. Any repercussions upon the price level and the volume of exports will only slowly come into effect. Thus, in the early stages at least, some decline of the yield of customs is almost inevitable.

Apart from the three sources of revenue considered, native and non-native direct taxes, and customs and excise, most territories derive a substantial income from licences of one kind or another, from royalties, and other miscellaneous sources. In Kenya 'licences and other taxes' provide about 17 per cent., and revenue from government property and royalties about 4 per cent. Mining revenue is important only in Southern Rhodesia and the Union. In the former, the colony now owns the royalties and in 1935 derived 14.1 per cent. of its revenue from royalties, the gold premium tax, and mining fees.¹ It has, of course, to make interest payments on account of the purchase price, but the transaction has now proved to be remunerative to the colony. In the Union the income tax, excess profits duty, and other revenue derived from the mines, have produced in recent years almost a third of the total revenue. Since the British South Africa Company own the mineral rights in Northern Rhodesia, the direct mining revenue is limited to the small receipts from licences.² But of a total assessment for income tax in 1936-7 of £205,530, as much as £191,828 was derived from companies the majority of which were concerned with mining. Nigeria received £188,242 from mining revenue in 1935. On the other hand, Tanganyika obtained only £42,830, Kenya £81,719, and the Gold Coast £97,729. It is not easy to estimate

¹ See above, p. 1436.

² See above, p. 1437.

accurately the proportion of the revenues of the Belgian Congo which is derived from mines. The government's share-holding in mining companies is, directly and indirectly, considerable,¹ and it would appear to have derived during recent years from a quarter to a third of its revenue from the mines, irrespective of the further taxation of incomes earned by mining.

The question whether mining enterprises have contributed as much as they might to the revenues from which further African development can be financed, is not easy to answer.² The fear of overtaxing struggling enterprises may reasonably restrict the imposition of duties upon imports of necessary machinery, or even of export duties upon the finished product. But if adequate provision is permitted for depreciation, it need not equally restrict the taxation of profits. It is true that the question has to be approached with some caution. Taxation sufficient to discourage further enterprise might check the inflow of capital, and therefore at certain times of customs duties, and might deprive the railways of the high-rate traffic which they urgently need. But a diminished reliance upon the taxation of capital imports, and an increased taxation of actually realized profits, might even stimulate such investment. For the rest, the natural resources of Africa are capable of profitable development just so far as relatively low-paid African labour is available to exploit them. It seems reasonable to hold that, subject to the need for avoiding the chance of discouragement to the industry, the largest possible share of profits from that exploitation ought to be made available to improve the welfare of the African population.

The relative merits of alternative means of increasing the yield of taxation have been widely discussed. For Kenya alone, they have been considered on no less than three occasions in recent years.³ It is evident that there are few areas in which it is easy to increase native taxation; all the indications appear to be in favour of effecting further graduation and adjustment rather than of increasing the general incidence. It is doubtful if anything is to be gained by substantially increasing the pitch of customs duties; to

¹ See above, p. 1455. ² For systems of taxation, see Chap. XXII, p. 1531.

³ By Lord Moyne in *Report*, op. cit., Cmd. 4093, 1932, pp. 13-16; G. Walsh and H. R. Montgomery, *Report on Native Taxation*, 1936; and Sir Alan Pim in *Report*, op. cit., Colonial 116, 1936, pp. 39-44, 231-5.

do so might retard the growth of the native desire for imported goods, the use of which has shown itself to be very susceptible to any change in price. Nor is it reasonable to expect any considerable increase in the near future from income-tax receipts. At present, the income tax must be regarded as a form of taxation suited only to the European and Asiatic communities and to the small number of natives who have adopted European commercial methods.

In South and East Africa all British territories except Tanganyika and Uganda have now imposed an income tax. There is no doubt that this tax is a more scientific form of levy than the graduated poll tax, and it also, unlike the poll tax, permits of the taxation of company profits; but the financial gain from making the change in those two territories is not likely to be important. While the rates of income tax in African territories are in general low as compared with those of European countries, it is important to consider the burden of taxation as a whole, rather than that of this one isolated tax. In Kenya, Lord Moyne's estimates of contributions by the different communities indicate that the taxation in 1931 was equal to about £41 6s. per head of European population of all ages. If the total of economically independent persons is taken as the criterion, the burden was approximately £64 per head.

It is not easy to compare these figures with those of European or other countries, since nowhere outside Africa is any similar distinction made of the income and the contributions to taxation of a small part of the whole community living on a higher standard than the average. The most superficial observer must be struck by the difference which the existence of a resident European community makes in the general standards of government expenditure. There is hardly a department of state activity in which expenditure is not forced up to higher levels than would be necessary for a territory in which the scale of requirements is judged by African instead of European standards.¹ There is consequently every justification for taxing Europeans up to the full limit of their taxable capacity. But though doubtless the rates on certain of the industrial undertakings could be raised, the agricultural section

¹ See *Report*, op. cit., Cmd. 4907, 1935, para. 115.

of the European community offers little scope for the imposition of high rates of income tax. Moreover, in any calculation of the possibilities of increasing the resources of the African dependencies as a whole, it will be seen that income tax must continue to form only a small proportion of the total revenues.

In a continent of great distances and comparatively sparse population, the cost of services such as administration, health, and education, must be high relatively to that of similar services in more closely populated countries. Present standards of technique of native agriculture and production, and the relatively small European populations north of the Zambesi, must imply, on the other hand, a low level of taxable capacity, even when every opportunity to profit by higher taxable capacity is seized. For many years to come the financial limitations upon African development must in consequence be stringent. It has more than once been necessary to make a reference to the experiences of the recent depression period. It is not out of place to recall here that in the British territories, excluding the Union and South West Africa, the total revenues fell from £27,971,000 in 1929 to £22,839,000 in 1932.¹ If during these years the development of the social services was retarded, there was one contingent advantage. In the process of retrenchment the colonial budgets were relieved of a certain amount of unnecessary commitments, and there was a definite stimulus given to the study of means for substituting less expensive agencies in administration; in particular, attention was directed to the possibility of making a larger use of African personnel. It is to be hoped that the expansionist sentiment which led to the large increase in loan commitments from 1925 onwards,² has now given place to a more realistic view of the financial possibilities of the territories. If so, there will also be a general recognition that, unless unexpected mineral discoveries or the like greatly increase the productive capacity of those territories, it is not possible to expect more than a slow and very gradual expansion

¹ The customs revenue, which reached its peak in 1928 with £10,834,000, continued to fall till 1934 when it was £6,854,000 (S. H. Frankel, *op. cit.*, Tables 38 and 39).

² The funded debt of the British territories other than the Union increased from £12,537,000 in 1913 to £63,699,000 in 1925; it had risen (partly on account of the depression) to £95,850,000 in 1932.

in the resources available for the development of the social services.

If African administrations are to be able to attain higher standards in expenditure on social improvements, the African population must pay the price which is necessary to earn them. Any substantial improvement in general taxable capacity will involve a far greater measure of differentiation in the constitution of society, the growth of specialized types of occupation, and the individualization both of effort and of the property which effort earns. There are those who will view with some distress anything which tends to substitute the 'disastrous atomization of western society'¹ for the organic unity which African society still possesses. It may be answered that western society is finding that it is possible to combine a common social purpose and ideals of common social service with an advanced degree of economic individualism. But whatever value is to be attached to this consideration, it is not open to doubt that the African peoples cannot hope to provide themselves with the resources needed for a material development of their social services, without a change in many of the social conceptions which determine the character of their economic life.

¹ J. H. Oldham and B. A. Gibson, *The Remaking of Man in Africa*, p. 53.

CHAPTER XXI

CO-OPERATIVE ORGANIZATION

I. THE USE OF CO-OPERATIVE SOCIETIES

VIEWED as an industry, agriculture has its own special needs in respect both of credit and of marketing facilities,¹ and the rural population presents its own distinctive problems in social development. The small farmer everywhere needs assistance in the purchase of seed and implements and the grading and marketing of his crops, and in backward countries especially, where he is ignorant and transport costs are high, he becomes unduly dependent on the middleman, who is frequently the money-lender as well. Co-operative organizations can so unite producers that they are able to borrow money on their joint liability, and they can secure, through joint purchase of agricultural implements and joint sale of crops, a fairer price from the merchant than the small farmer could obtain in isolation. The success of the movement in Asia and elsewhere has naturally suggested that in Africa also co-operation might solve some of the problems created by the impact of new forces on native life. Some caution is, however, necessary, for conditions are in many ways different; in particular the African peasant has as yet relatively little need for credit, and experience in India gives an emphatic warning against indiscriminate extension of credit facilities. There is, on the other hand, clearly great scope in Africa for the development of co-operative marketing schemes. There are those who take a wider view, and hold that through co-operation a fresh social equilibrium may be established in the African tribe to take the place of the old communal economy which is breaking down. In the words of a prominent supporter of this view, Africans need help 'to grow up socially and economically till they can face the modern world without disaster, and the village can welcome the foreign trader or teacher without fear of dissolution'.² If so, the co-opera-

¹ See Chap. XIII, pp. 909, 916, 963, 982-3.

² C. F. Strickland, 'The Co-operative Movement in Africa', *Journal of the Royal Society of Arts*, vol. lxxxii, 1934, p. 739.

tive movement will not in Africa always aim merely at an immediate economic end, but will include, in addition to societies for credit and agricultural production, others for thrift, promotion of education and hygiene, and 'better living' generally. Since a co-operator is a voluntary member of his society, whereas the tribal organization is by its nature compulsory, he will learn to consider himself a free agent and will realize that individual freedom can be compatible with the well-being of the community, which is an essential element in any social advance. As has been said, co-operation 'may be unable either to preserve or rebuild tribal society in its old form, but it may, however, help Africans to play a more active, self-respecting, and social part in the great economic changes that have to come to them'.¹

But experience is wanting on which to base an estimate of the possibility that these anticipations will be justified. Co-operation as applied to native African conditions has hardly as yet passed the experimental stage. Governments have approached the movement with some hesitation. Some administrations, when establishing organizations of this type for specific economic purposes, have felt that the achievement of these purposes rather than the encouragement of voluntary co-operation must be their primary aim, and have therefore made membership compulsory, thus departing in an important respect from the normal principles of the co-operative movement. Others have organized societies in a co-operative form, but have retained such a degree of control as to restrict the freedom of the members more narrowly than would be usual among a more experienced population. These limitations, however, do not prevent the development of a more advanced system at a later stage, provided they are gradually modified or withdrawn. The course so far taken by co-operative organization will be seen in the following study of the position in the different territories.

II. CO-OPERATIVE ORGANIZATION AMONG EUROPEANS

The organization of farmers for credit, supply, and marketing in those British territories which contain a European settled population—namely, the Union of South Africa, Southern Rhodesia, and Kenya, and, to a smaller extent, Tanganyika—rests principally

¹ M. Perham, *Native Administration in Nigeria*, 1937, pp. 294-5.

on the support of a Land and Agricultural Bank. Though co-operative societies among Europeans had already existed in South Africa for some years, it was not until the creation of the Land Bank in 1912 that progress became rapid. The Bank, instituted originally for granting loans to individuals, extended its operations to the financing of co-operative bodies. The agricultural societies, formed chiefly for the purchase of live-stock and other requirements and for the marketing of produce, numbered 388 in 1934, but for various causes were reduced to 375 with 86,300 members in 1935. They are assisted by a Registrar of Co-operative Societies and a staff of inspectors. There were also 13 consumers' societies in urban areas with 13,500 members, and a large number of small rural credit societies, amounting in 1933 to 1,280, registered under the Agricultural Credits Act of 1926, but these are regarded as unsuccessful and likely to be liquidated.

The agricultural societies and the rural credit societies, both of which are financed by the Land Bank, admit only European members, and it has been laid down that a native society cannot be registered under the Co-operative Societies Act, 1922. Three advances from the Land Bank were for the first time made to Africans in 1935. The Act of 1922 was amended in 1925 to provide that in any area where 75 per cent. of the growers of a stated product together owning 75 per cent. of the crop are members of a co-operative marketing organization, the minority of non-members may be required to sell their own produce of that description through the same co-operative channel. This provision, commonly known as 'compulsory co-operation', was reviewed by the Commission appointed by the Union Government in 1933 to report on co-operation and agricultural credit. The Commission¹ recommended that since the 'compulsory' power led to imprudent attempts to control the price of produce it should be withdrawn. Other recommendations were that the Land Bank should be placed on an independent footing, and should raise its own working capital instead of being financed by the state, and that suitable legislation should be passed to encourage the formation of native co-operative societies.

¹ *Report of the Commission to inquire into Co-operation and Agricultural Credit*, U.G. 16, 1934, chap. iii. .

In Southern Rhodesia two laws govern co-operation: Act 7 of 1909, providing for registration of co-operative societies, and Act 34 of 1925, dealing with co-operative companies. The latter term was used to indicate an institution with limited liability, the liability of societies being then unlimited. A Land Bank was set up in 1924, and eight societies or companies are mentioned in the Bank's report of 1935. The total number on the register is not stated. The British South Africa Company also set up a Land Bank, with offices in Bulawayo, which originally financed farming ventures, though now it is confined to house building.¹ In Northern Rhodesia the government has agreed to pay half the salary of a secretary grader for the Northern Rhodesia Tobacco Co-operative, on condition that his services shall be available to all tobacco planters in the western area, and the Abercorn Co-operative Society has been founded to deal with the marketing of the entire coffee crop. The North Western Rhodesia Farmers' Co-operative Society and the Northern Rhodesia Livestock Society operate in connexion with the Maize Control Board and the Cattle Marketing Board respectively.

The Land Bank of Kenya was established in 1931, when a few co-operative bodies had already been formed by European farmers for supply or sale and had been registered under the Companies Ordinance. The Co-operative Societies Ordinance of 1931 differs from the corresponding statutes of Southern Africa and resembles those of British colonies in Central Africa, in so far that it follows the model of British India rather than that of Great Britain or the Netherlands. Six societies, with 2,000 European members, are now registered under it. The Land Bank makes advances to these societies and to European settlers; some facts showing the scale of its operations are given on page 822 of Chapter XII. The Kenya Farmers' Association is the largest organization of the co-operative type in the colony, and now includes, in its fourteenth year, a membership of 934. It is not clear whether the Association, which was originally incorporated under the Companies Ordinance, has now been brought under the Co-operative Societies Ordinance or not; its trading surpluses are, however, distributed to the members in accordance with their patronage, and its methods are co-opera-

¹ See Chap. XII, pp. 819-20.

tive. The Association operates a wheat pool and a maize pool; its balance-sheet shows a capital of £175,000, of which one-half is owned by the members in the form of paid-up shares and reserves. The Association considered in 1936 a proposal that the Coffee Board, Sisal Board, creameries, and other organizations should be invited to join in the co-operative export of produce, and a single association of primary producers created.

In Tanganyika the Co-operative Ordinance makes the same provision for compulsion as the 1922 Act in South Africa, but no action has been taken on it in view of the fact that there is a large native production to be reckoned with. An attempt was made in 1937 to amend the law so that the section could be applied to any class, tribe, or division, but it was not carried through. No bulk sale of produce through a co-operative organization can be successful unless all the producers in an area are comprised, but a co-operative society consisting of natives and non-natives is not at present a practical proposition. The object could perhaps be achieved by creating separate societies of natives and non-natives which would perform all the bulking, collecting, and payments, with some central organization to arrange the actual sale.

III. CO-OPERATIVE ORGANIZATION AMONG NATIVES IN SOUTHERN AFRICA

Co-operation for Africans in South Africa was first proposed in 1908 by a resolution of the Transkeian Territories General Council, and a draft proclamation, authorizing the formation of credit societies, was submitted to the Union Government in 1911. Following propaganda by the Rev. B. Huss¹ a number of societies were founded in the Transkei area, and proclamations were again submitted in 1926 and in 1930. A request for supervision by the registrar and inspectors of the Union was not granted; instead, a Proclamation, No. 191 of 1934, was issued, providing for the establishment of a Central Committee under the Transkeian General Council to register and supervise the societies. A sum of £200 was voted by the Council to meet the expenses of the Committee and of a supervisor, and 37 societies with a capital of £25,000 derived from shares and deposits have been registered with the

¹ The Rev. Bernard Huss, *Peoples' Banks*, 1928.

Committee. The Commission on Co-operation¹ of 1933 found that certain societies had made mistakes in paying unduly high interest on deposits and charging too high a rate on loans, but that 'having in mind the communal mode of living among tribal natives, it should not be difficult to secure a true spirit of co-operative enterprise among them'. The Commission also pointed out that credit societies would be followed by organizations for co-operative selling and buying, and recommended that the proclamation should extend to these activities; it should also be so elastic as to be applicable to all scheduled native territories in the Union. Proclamation 191 of 1934 is, however, limited to the Transkeian Territories and to credit societies. Native farmers' associations are also found in the Transkei; their object is principally the improvement of agricultural methods, but a small amount of trading has been done. The only important society among urban Africans is the Western Native Township Co-operative Society, a consumers' store formed in 1932 in a native area of Johannesburg. Its first year's trading was successful, and though some losses have ensued, the promoters are declared by the European advisers to be capable of learning by experience and to be building up a sound co-operative society.² Similar ventures are now being encouraged in native locations outside Johannesburg. Such societies remain unregistered.

There is no native co-operation in Basutoland, Bechuanaland, or Swaziland, nor in South-West Africa. Attempts were made to form societies in Basutoland, but they failed; they are now aiming at societies for the classing and sale of wool, a matter of great importance in this area. African growers of tobacco in Swaziland have been required to sell their produce through a European co-operative company in accordance with the law of 'compulsory co-operation', and are represented by an Assistant Commissioner on the board of the company, but are not themselves eligible for membership. No native societies have yet been instituted in Southern Rhodesia.

IV. NATIVE CO-OPERATIVE ORGANIZATIONS IN BRITISH COLONIAL TERRITORIES

In Northern Rhodesia Ordinance 114 of 1914 authorized the organization of co-operative societies; it is of the type usual in the

¹ *Report*, op. cit., U.G. 16, 1934, para. 1025.

² W. G. Ballinger, *Race and Economics in South Africa*, 1934, p. 63.

European communities of Africa, and no native societies appear to exist. Nyasaland has as yet no organization for co-operation. Tanganyika is remarkable for the Native Co-operative Union, which unites the primary societies of the Chaga tribe on Mount Kilimanjaro, supplies them with spraying material and other requirements for their coffee plantations, and markets their crops of *arabica* coffee and certain minor products. The Union received considerable impetus from the opposition by Europeans shown at one time to native coffee growing; in 1937 there were 27 societies affiliated, with roughly 24,000 members. A European manager is employed, and about 1,200 tons of coffee were sold in 1936. There had been a Kilimanjaro Native Planters Association founded in 1922, but this fell into disorder by 1930, and after reorganization in 1931 was registered as the Native Co-operative Union in 1932.

This action was taken under Ordinance 207 of 1932. The Tanganyika Government, after passing the Ordinance and issuing regulations under it adapted to the needs of native co-operative societies, deputed an officer to study the co-operative movement in India and Ceylon. This officer is now available to advise any societies which may be spontaneously formed, but there is as yet no special staff for the encouragement of the movement. The Native Co-operative Union is now part of the government machinery for organizing the marketing of native produce, and under powers granted by the central government, the chiefs have ordered the people to sell their coffee to it. It has assisted the native authorities in enforcing their rules for the cultivation of coffee, the protection of the water supply, and the prevention of soil erosion; the Provincial Commissioner in 1934 declared that the Chaga understood the value of co-operation, and that 'the progress reported in previous years has continued, and the attitude of mind of the mass of the people has materially altered for the better'. Lately, however, there have been some signs of disruption. Throughout 1936 there was growing discontent among the natives, which culminated in rioting in the Moshi District in 1937. The rioters complained that owing to heavy overhead expenses the Union paid lower prices than they could obtain outside. In this connexion it is interesting to notice that the German produce buyers some-

times offer between 10 and 15 per cent. above market prices on condition that the sellers take part repayment in German goods, especially agricultural implements. An attempt to undermine the authority of the chief of Machame may also have been at the back of the riots, making them therefore not purely economic.¹

A marketing society for the sale of coffee has been formed among the Bugufi growers in the Ngara sub-district of Biharamulo in Tanganyika, and in 1936 the Ngoni-Matengo Co-operative Marketing Society was registered; it markets the native tobacco and coffee crops in the Songea area. Native settlers at Chasalawe have set up a credit society with the aid of a loan from the Kwimba Native Development Fund, but though the grant of credit to Africans by private lenders is closely restricted by law, no general need for credit societies is felt, and indebtedness is not heavy. Ghee societies are being started among stock-owning tribes in the Kwimba and Mbulu Districts. In Uganda there is a large coffee co-operative in Bugisho, and a Co-operative Societies Bill has recently passed its first reading.

In Kenya, on the other hand, there are no co-operative institutions among natives, and the Co-operative Ordinance is somewhat better adapted to the needs of Europeans than to those of Africans; the fee for registration of a society in Kenya is 25s. as against 3s. in Tanganyika. It is possible that the steps now being taken to stimulate the production of milk and ghee in the native reserves, and to promote the industry in hides and skins, may lead to the development of co-operative institutions. There is, however, no co-operative staff in Kenya, and Sir Alan Pim has recommended² that an officer be trained for such work even in the early stages of the movement. Credit and stores societies, he considers, should be deferred to a later stage, agricultural improvement and thrift being the first necessities. He takes, however, a wide view of what is required. 'Village life must be improved in all directions, and not only the agricultural but many other departments, including more especially the medical and the educational, are concerned in this all-embracing work.' Unsupervised attempts at co-operation have been proved in Kenya to involve risks, and though

¹ See *Report to the League of Nations on Tanganyika Territory*, 1937, pp. 206-13.

² *Report on the Financial Position and System of Taxation in Kenya*, 1936, pp. 173-5.

co-operative stores may be successfully conducted at a Jeanes training centre,¹ instructions have been issued to African teachers not to open co-operative stores without sanction after return to their schools in less accessible places.

In Nigeria the Agricultural Department encouraged the formation of co-operative societies, at first largely with the object of improving the grade of the cocoa crop, though a wider view developed later. Several societies were started, and in 1935 the Co-operative Societies Ordinance, based partly on Asiatic models, was passed to enable the government to consolidate the existing organizations and to extend the movement beyond the agricultural field. A registrar with special training has been appointed, and proposals for the formation of a Co-operative Department are being considered. The amount of cocoa marketed through the societies in the 1936-7 season was 3,698 tons, and the quality, as in the Gold Coast, is high. The membership is about 6,500, and associations number about 100. Reorganization is proceeding, and thirty societies are now affiliated to the Ibadan Union. Official control has been less close in Nigeria than in the Gold Coast, and though lower efficiency may have resulted, it is possible that a fuller sense of co-operative independence has developed. The societies are primarily for marketing, and have limited liability, but they give credit in small amounts from their own resources. The rate is high, usually about 15 per cent., but as there is little security the societies are taking a considerable risk, for which they have to be covered. This combination of credit and marketing facilities in the same society is unusual, but it is to be found also in the Gold Coast, where conditions are similar. The small cocoa farmer has little need of credit on a large scale, as his equipment is cheap; also as land is seldom held on a negotiable title there is no security to be pledged, beyond the export crop itself, and it is therefore natural that the society marketing that crop should also furnish such credit as is necessary. The mixed farmer of Northern Nigeria, on the other hand, does need loans, which are at present granted by the native administrations. It is now under discussion whether the issue of these loans could advantageously be taken over by co-operative societies. The Nigerian Government is also putting

¹ See Chap. XVIII, p. 1228.

forward proposals for the formation of co-operative societies for the marketing of palm products; their principal object would be the purchase of a palm-oil press for common use. There are also in Nigerian towns and villages a large number of thrift and mutual aid societies which offer an opportunity to the co-operative organizer.

In the Cameroons under British Mandate, 93 cocoa societies in Kumba, affiliated to a union, had 1,568 members in 1936, and sold 456 tons of first-grade cocoa. About 90 tons was also sold by 41 new societies in Mamfe, though these were not truly co-operative. The Kumba societies and union own a lorry and finance the cocoa cultivation of their members; over £3,000 was loaned in 1936. Reorganization is proceeding as in Nigeria, and the villagers are said to appreciate the advantages of joint action.

The Gold Coast Colony has developed co-operative societies for natives on a larger scale than any other British territory in Africa. The Co-operative Societies Ordinance of 1931 was based on Asiatic legislation, and is well suited to the needs of West Africa. The Ordinance did not, however, provide for unions of societies, and it has recently been amended to authorize the formation of such bodies, in order to increase the credit facilities available. Some 400 primary societies of cocoa growers in 1936 contained 9,000 members and possessed a capital of £25,000, almost the whole of which has been contributed by the members in the form of shares and reserve funds. A deposit system has also been developed and the total deposits in 1936 amounted to £24,000. The cocoa marketed, about 6,000 tons, is of high quality, and a marked improvement in the standard of produce effected through better processing and grading is the most important benefit conferred by these societies on the growers. Joint marketing committees, which numbered twenty-nine in 1935, undertake the business of bulking and sale on behalf of the societies. Like the Nigerian societies, those of the Gold Coast combine credit and marketing facilities. Advances are given to individuals for cultivation, and overdue payments are few. Recently the societies have begun to issue loans for the relief of farm-mortgage debt, and up to the present these loans and personal and cultivation loans have amounted to £30,000.

The movement has in the Gold Coast remained closely attached

to the Agricultural Department. The societies have from the first been closely supervised by the registrar and a staff of European and African officers. The scarcity of African villagers competent to write the accounts of a credit and marketing institution has necessitated the employment of paid secretaries for groups of societies in certain areas, but classes are now being held in order to educate villagers for this duty wherever possible. Few societies were registered before 1935, as their success was not yet established; the whole position was, however, examined in 1934 by an adviser¹ from the Tropical College of Agriculture, Trinidad, on whose recommendation the control exercised over the sound societies is being relaxed, while unsatisfactory societies are being dissolved. An annual audit of every society is conducted by the official staff. A small number of societies for the cultivation and marketing of cotton, fruit, copra, and rice are in operation with varying success; there are also two thrift and loan societies whose membership is restricted to the staff of the Department of Agriculture. The movement has hitherto been limited to agricultural credit and marketing, and other branches of co-operation have not been developed. Africans in the towns have their own thrift and loan societies on an informal and unregistered footing, and the organization of these societies on regular lines would seem to offer a suitable field of activity for the Co-operative Department. Occasional attacks are at present made on the co-operative movement by educated Africans, who allege that European firms are favoured in the cocoa auctions, though this allegation has been vigorously denied. In 1937-8 a grave setback was sustained by the movement when an agreement between the buying firms was met by a complete boycott on the part of the growers. As was shown in Chapter XIII, in dealing with this incident,² the situation is being investigated by a commission of inquiry.

In Togoland under British Mandate a group of cocoa societies under the control of the Gold Coast registrar has made some progress. Twenty-one primary societies and two joint marketing committees were working in 1935. There is no co-operation in the Gambia, and the first attempt to organize rice-growers in

¹ C. Y. Shephard, *Report on the Economics of Peasant Agriculture in the Gold Coast*, 1936.

² p. 908.

Sierra Leone was made in 1936. A demand for a wider interpretation of the movement than has prevailed in the Gold Coast has been made by urban Africans of Sierra Leone.

V. THE ORGANIZATION IN FRENCH TERRITORIES

The organization of Africans for joint economic action and mutual benefit in the French colonies has mainly taken the form of *sociétés de prévoyance*. These institutions, which were authorized in the older colonies in 1901, are compulsory, a contribution (*cotisation*) being collected from each cultivator with his tax. The older decrees were replaced by a succession of measures of the Central Government of French West Africa, dating from 1919 to 1933. According to these, the objects of the societies are to develop agriculture, animal husbandry, the production, processing, and sale of crops, to give short-term loans to their members for any useful purpose in time of need, and to make advances, of longer term if necessary, for the conduct of agriculture or animal husbandry or for the purchase of equipment. There is one society for each administrative circle, the secretary-treasurer is appointed by official order, and the District Administrator, who is the president, represents the society on its executive side. A council of administration, elected by the members, has an advisory function; similar committees are elected in the sections 'according to local custom'. The council under its official president having drawn up its budget of expenditure for the coming year, the government fixes the amount of contribution required to meet this expenditure, and levies it accordingly. The receipt of deposits is not permitted, but loans may be taken with the approval of government, and the Agricultural Loan Board (*Caisse Centrale de Crédit Agricole*) in each colony is authorized to lend to the societies.

The *sociétés de prévoyance* have attained considerable numbers and handle large funds. In French West Africa there are stated to be such *sociétés* in 101 out of the 118 circles, with 8,500,000 members. Their resources consist of members' contributions, grants of facilities (e.g. seconding of officials) from the colonial governments, and loans from the Agricultural Banks. The *sociétés* of Senegal at the end of 1934 had 1,200,000 members paying an annual contribution of 4,500,000 francs. Those in the

French Sudan had in 1936 a total of 1,005,396 members and a budget of 2,114,033 francs.¹ The *sociétés* in Dahomey are also flourishing. Whereas in French North Africa the *sociétés de prévoyance* aim at the prevention of famine by means of compulsory thrift, those of West Africa were directed by M. Brévié as Governor-General towards a bolder policy. Improved seed is multiplied and distributed to members, loans in cash and kind are made, breeding animals are bought and maintained for their use. Under this policy the *sociétés* have become one of the principal agencies in the recent programme for the extension of native production.² A typical instance is seen in the expansion effected in the groundnut crop in Senegal, where the *sociétés* have been instrumental in building a large number of wells for the improvement of the water supply,³ and undertake the direct marketing of the crops. A standard price is paid to the cultivator on delivery followed by a bonus on the completion of the sale.

The degree in which the opportunities offered by the *sociétés* are utilized by the members no doubt varies from one circle to another, and much may depend on the attitude of local officials; but the figures quoted leave no room for doubt that striking results are achieved. Criticisms have been directed against the new policy by Chambers of Commerce and the press, which make much of embezzlements and shortages revealed in certain Senegal *sociétés* and demand that their activity be limited to the improvement of agriculture and animal husbandry; the motive behind the opposition is perhaps seen in the claim that the attempt to sell the produce of the members directly and without the intervention of local merchants be abandoned. Comment is made on the participation of officials in such trading business. On the other hand, a distinguished officer who was sent out from France to conduct an inquiry on the spot reported substantially in favour of the *sociétés*.

In Togoland⁴ and the Cameroons under French Mandate the *sociétés de prévoyance* show some difference in organization. In Togoland there are now 6 societies, with a budget of 340,000 francs, the *cotisation* varying from $\frac{1}{2}$ to $2\frac{1}{2}$ francs per member.

¹ *Premier Congrès Soudanais*, 1936, vol. ii, p. 135.

² See Chap. XI, p. 633.

³ See Chap. XV, p. 1051.

⁴ *Rapport annuel au conseil de la Société des Nations sur l'administration du Togo, pour l'année 1937*, pp. 66, 194.

The societies have received loans of 130,000 francs from the state, and considerable aid in the form of motors and machinery. Their principal activity lies in the provision of palm-oil crackers for village use, but they have lately made an interesting departure in the construction of co-operative tapioca factories. In the French Cameroons the system does not differ in any material respect from that observed throughout French West Africa; the annual *cotisation* (now raised to 2 francs) is collected from members at the same time as their tax. The president of each society is the administrative head of the district; but, as in French West Africa, the annual budget is discussed at meetings representative of the members. The societies are thus in practice official organizations, like those in other French territories; but the system has the advantage of engaging the interest of those who contribute to them, and they have a wide field of activity. The earliest society, founded at Dschang in 1924, was concerned with the breeding of cattle; later societies undertook the purchase of implements, the planting of coffee and cocoa nurseries, and the joint sale of produce. The societies now maintain some 17 *surveillants agricoles* and a considerable number of *moniteurs de culture* locally trained; the societies at Nyong and Sanaga had between them as many as 150 *moniteurs* in 1935. They buy a considerable amount of agricultural machinery and equipment, such as palm-oil crackers, sprayers, and ovens for cocoa, coffee driers, and the like; they have lately added the improvement of live-stock to their activities. They are financed mainly from their own subscriptions, and are entitled to borrow from the Agricultural Bank, but the figures given in the annual reports of the territory do not discriminate between the different classes of receipts. There were at the end of 1934 forty-four societies; their expenditure in 1935 amounted to 1,579,728 francs, and they had a balance of 487,579 francs. There are in addition five societies of European planters.

An Agricultural Loan Board (*Caisse Centrale*) in each colony of French West Africa, already authorized by a Decree of May 23, 1926, was given wider powers by a Decree of July 10, 1931, and *Caisses* have been established in Dahomey, Guinea, the Ivory Coast, Senegal, and Sudan. A similar bank in the Cameroons was established by a Decree of June 4, 1931, and another in Togoland in

1935. The banks are permitted to lend to *sociétés de prévoyance*, co-operative societies, and individuals. The Permanent Mandates Commission in 1932 was informed that their principal object was 'to help planters', and it would seem from later reports that in the Cameroons at least the loans given by the local *Caisse* were nearly all of this character. Elsewhere there are no figures available showing the extent to which loans are given to the native *sociétés de prévoyance*. In French Equatorial Africa no *sociétés de prévoyance* exist. An Agricultural Bank finances plantation enterprises; interest rates are often exorbitantly high.

Mutuelles scolaires have been encouraged in the West African colonies since 1916, and a government circular of January 28, 1936, reviews their progress. All the pupils of a school are members, the headmaster is the president under the supervision of the *Commandant de Cercle* and the Education Department. Their business is to engage the pupil members in joint work on the land or in a craft, to teach the lesson of mutual aid and the benefits of agriculture. Many are said to be working effectively. The *mutuelle scolaire* of Africa is modelled on the French *mutuelle scolaire*, and resembles in several respects the Young Farmers' Clubs of Great Britain and North America. It differs in insisting on a joint enterprise of the members, whereas the club expects each member to manage his own live-stock or garden plot and to compare notes with his fellows.

VI. THE ORGANIZATION IN BELGIAN AND PORTUGUESE TERRITORIES

In the Belgian Congo a Decree of March 23, 1921, applied the Belgian law on co-operative societies to the Congo territory. Several societies of employees have been approved. The Coquilhatville Co-operative Supply Society admits employees of government, of the *Banque du Congo Belge*, and of religious or philanthropic bodies. The members are for the most part, and perhaps solely, Europeans. There has been a protest by the Chambers of Commerce against loss caused to them by these societies. There are a number of African co-operative organizations, mostly started by government action.

A Law of July 21, 1928, in Moçambique provided for the creation of an agricultural credit fund in that colony.

VII. GENERAL CONCLUSIONS

If co-operation be viewed primarily as an agency of economic improvement, its chief function in Africa appears at present to lie in the formation of marketing societies with limited liability. Credit societies with unlimited liability run some danger of misuse in a primitive community, and, save in part of the Union, a few districts in coastal West Africa, and in some urban centres, there seems little present need for the provision of credit facilities. Indebtedness is mainly confined to these areas, and even there the burden is not as heavy as in India or Ceylon. There is as yet no procedure in African customary law for regulating money contracts or interest-bearing loans, and the absence of individual tenure reduces the possibility of borrowing on the security of the land.

The problems which arise from the development of a system of individual tenures have been discussed elsewhere,¹ and particular reference has been made to the effect which the recognition of individual titles may have on the use of land as a basis of credit. Though, however, credit facilities are not yet required on any large scale at present, there will be some greater need for them in future as agricultural methods improve, especially in mixed farming. But care must be taken not to tempt the African into unnecessary borrowing by the provision of easy loans, and it must also be remembered that the conduct of credit societies imposes a greater strain on the honesty of members than the organization of production and marketing. The joint credit and marketing societies of Nigeria and the Gold Coast would seem to offer adequate means for meeting, at all events for some time to come, all requirements of this nature.

Up to the present there are, as has been shown, relatively few societies which can be described as genuinely co-operative, in the sense that they are voluntary and self-managing, but though the wider advantages which many see in the movement may depend on the growth of independent institutions, there is not yet sufficient material on which to base a forecast of the capacity of the African to conduct voluntary institutions of this class. It can, however, be

¹ See Chap. XII, pp. 842-63, 867-76.

justly said that experience in Nigeria and the Gold Coast shows that natives can appreciate the advantages of voluntary combination for a common purpose. The numerous organizations of an official character, or mainly directed by officials, while not in the full sense co-operative, nevertheless have a value beyond the immediate economic benefits which they secure; they stimulate the interest of their members and demonstrate the value of joint action, thus affording a foundation for the growth of the true co-operative spirit. It must also not be forgotten how essential official supervision is in the early stages. After initial popularity, co-operative movements are apt to suffer a setback, and constant care and encouragement are needed. In some cases a general improvement in prices seems to remove the need for joint marketing; in others a sudden depression will make it difficult for a credit society to recover its outstandings, and its resources are in consequence depleted at the moment when its members have most need of its aid. It is at such times that the middleman or the money-lender finds ways to reassert his control. There is another consideration which must always be present in the minds of those who interest themselves in the promotion of co-operative organization. At present the needs of the small farmer are few, and the co-operative movement will not ultimately endure if it aims merely at giving him more money, for indolence may well triumph. Rather it must encourage saving, and expenditure of the extra money on productive purposes or 'better living'.

There are some who, while acknowledging the advantages which may be expected from the extension of the movement, have hesitated to support it, on the ground that the existence of the co-operative society may be incompatible with the position accorded to native authorities under the system of indirect rule. It is felt that such societies represent groups of persons united by common interests and loyalties not shared by the rest of the community, so that their existence may tend to loosen those tribal bonds on the maintenance of which the evolutionary development of native societies depends. But that consideration cannot be decisive. Any native tribe contains within itself groups which unite for common purposes, and acquire, in consequence, a sense of common interest which may be opposed to the interests of other members of the

tribe; the creation of a new combination to meet new circumstances does not necessarily militate against any existing loyalty. There is, of course, the possibility that, representing as it probably would the more progressive elements of the tribe, the society might become a focus of opposition to traditional authority, and recent experience in Tanganyika shows that there is real risk of conflict; but this danger is reduced if a link is maintained between the native administration and the society; for example, by representation of the native authority on its committee. Such interaction may indeed serve to strengthen the native authority while proving of benefit to the members of the co-operative society.

CHAPTER XXII

MINERALS AND MINES

I. INTRODUCTORY AND HISTORICAL

AFRICA's minerals have had a great influence on the history of the continent. In the remote past it was the search for precious metals which established contact with Asia and Europe; in the present age it is the metals and precious stones more than any other of Africa's products which have been responsible for the introduction of capital and all that this has meant. With few exceptions mining operations have been left to private enterprise; governments have for the most part confined their activities to assisting in the discovery of minerals by the collection and publication of geological information, to regulating the terms under which prospection and production may be carried on, and to supervising conditions of recruiting and employment of labour. The marked differences in the quantity of minerals produced in the various territories may be primarily due to inequalities in the distribution of mineral resources. But the extent of actual production does not necessarily offer a reliable indication of a country's potentialities, for the discovery and exploitation of minerals are largely affected by the degree of general development, particularly of transport facilities, and by the nature of state policy in its various aspects, while not infrequently factors such as premature expansion and unsound finance have materially retarded progress for a considerable period. After a survey of the progress that mining has made in each territory, it will be necessary to discuss the chief of these influences upon the growth of the industry.

The native working of metals in the pre-European period is worthy of mention, not only for its historic interest, but also because the traces of ancient workings have in more than one area afforded a valuable guide to modern prospectors. Long before the Christian era gold deposits in Ethiopia were known to seafaring races trading on the shores of the Indian Ocean, and the 'odour of gold', to

quote the Portuguese historian, João de Barros, attracted Arabs to settle on the south-eastern coast.¹ Glowing accounts of mineral wealth stimulated numerous Portuguese expeditions into the coastlands and interior of Monomotapa and Sofala. They found natives extracting gold by primitive methods and carrying off in quills the few grains which they had won. In Southern Rhodesia the 'ancient workings' are certainly of remote origin, and engineers estimate that the people who made them must have worked out 100,000,000 tons of rock.² As recently as the Matebele invasion of Mashonaland the Amahole worked for gold between the Umsweswe and Umfuli rivers, and the tradition that rich ground was to be found in the old diggings of Southern Rhodesia guided concession hunters; it has been estimated that more than nine-tenths of the mines worked since European occupation are located on the sites of these excavations.³ In Northern Rhodesia also the old mine workings scattered over a wide area guided the first prospecting party sent from Bulawayo in 1899, which pegged the Kansanshi Mine and located many of the large copper deposits in Katanga.

On the West Coast the natives have extracted gold and have worked tin deposits in Northern Nigeria for an unknown period. In the fourteenth and fifteenth centuries the gold for the coinages of Portugal, Spain, and Italy came exclusively from West Africa.⁴ Elizabethan England, when it thought of Africa, spoke, in Ancient Pistol's phrase, of 'golden joys', and the guinea took its name from the coin struck in the seventeenth century by the company of Royal Adventurers of England trading in Africa. As will subsequently be seen, the exploitation by Europeans of the West African gold field was due to the discovery that mines were still being worked by the natives, and the same is true of the tin deposits in Nigeria.

In surveying the development of mining in the modern period and the variety of methods adopted there is one preliminary

¹ S. R. Welch, *Europe's Discovery of South Africa*, 1935, p. 58.

² T. A. Rickard, *Men and Metals*, 1932.

³ A. MacGregor, 'Mines and Mineral Resources of Southern Rhodesia', *Sands, Clays, and Minerals*, vol. ii, no. 4, 1936, p. 48.

⁴ G. Daumain, 'L'or en Afrique occidentale française', *La chronique des mines coloniales*, Sept. 1933, and N. R. Junner, 'Gold in the Gold Coast', *Gold Coast Geological Survey*, Memoir no. 4, 1935.

observation which needs to be made. It will be obvious that development has been determined not merely by local circumstance, but partly also by national characteristics. The British had a large experience of organizing mining enterprise in a great diversity of conditions; prospectors were readily forthcoming wherever it seemed likely that minerals could be found, and the London financial houses and investing public were always interested in their activities. Those conditions did not prevail to the same extent in French, Belgian, or Portuguese territories, where the private prospector has been less in evidence and development has often had to wait on government initiative or support.

The type of development adopted will be apparent from a study of the main facts which at present characterize mineral production in the different territories. In making that survey it will be necessary to mark the distinction between the course taken by the production of gold and that of other metals. As a commodity gold has the advantage that the producer is always sure of a market at a relatively stable price. The only dramatic change in the price of gold which has occurred over a long series of years, that due to the devaluation of a number of currencies, resulted in great advantage to the industry. While the prices of other metals are liable to rapid changes, often due to causes lying outside the metal market itself, the producer of gold is limited in his risks to factors confined to his own particular enterprise. That so large a part of the production of certain areas consists of gold has had a marked influence on the flow of capital to them and on the stability of their economic conditions. It will further be necessary, in examining the facts in different territories, to treat of diamonds separately. The diamond industry is regulated by exceptional conditions. Those who have incurred heavy outlay in development are always at the risk of a chance discovery which may flood the market with cheaply produced stones, or of a change in demand which may mean an expensive accumulation of stocks. They have therefore found it necessary to incur large expenditure in securing a monopoly of supply or in keeping supplies off the market; indeed, the cost of limiting production must in some periods have exceeded that of production itself.

II. MINERAL DEVELOPMENT IN DIFFERENT TERRITORIES¹(a) *South Africa*

Gold. The earliest systematic effort to discover minerals was made by the Dutch East India Company, which introduced miners and assayers from Europe in 1669 and succeeded in tracing the source of the copper ore which natives had brought down to Capetown from Namaqualand in 1681. No steps were, however, taken to develop this, and subsequent prospecting was in South Africa left to private enterprise. Almost from the first days of colonization it was suspected that the Transvaal was rich in minerals, but in spite of the offer of £5,000 for the discovery of a really rich gold occurrence and the attempt to attract smelters for copper and iron from Germany, no development took place until the German geologist, Carl Mauch, reported gold in Mashonaland (Southern Rhodesia) and at Tati, now included in the Bechuanaland Protectorate, where a small stamp-mill was set up as early as 1869.² These discoveries and the finding of diamonds at Hopetown in 1867³ greatly stimulated prospecting, and the next twenty years saw a small gold rush to the alluvial gold fields of Lydenburg, the opening of the Sheba Mine at Barberton, and the beginning of reef-mining on the Witwatersrand in 1884. Henceforward development lay in the hands of large capitalistic enterprise.

Up to the end of 1936 the Union is estimated to have produced minerals valued at £1,969,000,000, of which gold contributed 75.6 per cent., diamonds 16.2 per cent., coal 5.4 per cent., copper 1.5 per cent., and tin, silver, asbestos, and other minerals the remainder. It contributed 41.9 per cent. of the world's production of gold in the period 1903-34. The most important gold-bearing formation is the Witwatersrand. Here the 'reefs' are beds of conglomerate, composed mainly of quartz pebbles bound together by a siliceous cement containing iron pyrites, the whole being called 'banket'. The occurrence of gold in this sedimentary deposit over a wide area presented engineers with

¹ For a fuller discussion of the development of the gold and other mineral industries see S. H. Frankel, *Capital Investment in Africa*, 1938.

³ G. F. Williams, *The Diamond Mines of South Africa*, 1902, vol. i, p. 119.

new conditions, for hitherto most of the world's gold output came from alluvial deposits and quartz veins. While the Rand is the most consistent field yet found, considerable fluctuations in value occur, and in all mines a large proportion of the ore is low-grade. In the early days of the field only the outcrop was worked, but of later years the mining of low-grade as well as rich ore at great depth has been undertaken, with greatly enhanced costs of exploitation. One property is now being worked below 8,000 feet. These disadvantages could not be overcome save by the employment of a competent technical staff, costly equipment, and an expensive programme of exploration and mining. Individuals and small companies had been able to work the outcrops, but within a few years of the 1889 boom it had become clear that the development of gold mining on the Rand, unlike that of the diamond industry, which had flooded South Africa with relatively easily-won wealth, implied the establishment in the interior of the country of a highly organized modern industry requiring large amounts of capital and labour.¹ Over-promotion, over-capitalization, and over-speculation had caused loss of confidence and resulted in periods of deep depression; in 1893, out of 183 gold-mining companies in the Transvaal, 104 had produced no gold.²

The necessity of ensuring stability in finance and efficiency in working led by gradual steps, beginning in 1897, to the adoption of a system under which the assumption of control by powerful financial corporations ensured the 'rationalization' of the industry. Out of 576 gold-mining companies floated on the Rand during 1887-1932, a total of 206 were amalgamated, 313 were wound up, and only 57 remained in existence in 1932. In addition, 160 companies had so short a life that their history cannot be reliably traced. With some minor exceptions the 57 which survived were all controlled by six financial houses or groups. When group control was introduced, the average yield of gold over the whole industry was 11.4 dwt. per ton milled and working costs were 29s. 6d. a ton. By 1929 the cost (in spite of largely increased

¹ S. H. Frankel, *op. cit.*, chap. iii, pp. 75 ff.

² *Group Administration in the Gold Mining Industry of the Witwatersrand*. Address by J. Martin before the Economic Section of the British Association for the Advancement of Science, Johannesburg, 1929.

costs in miners' phthisis compensation, higher wages to European miners, higher customs rates, and greater depth of workings) had been reduced to 19s. 9d. per ton milled, and the industry, notwithstanding the reduction in the average yield of gold to 6.55 dwt. per ton milled, remained on a remunerative basis. In the period 1886-1932 the Rand absorbed some £200,000,000 of capital, produced gold to the value of £1,145,000,000 and paid £255,000,000 in dividends.¹ These results, and the ease with which capital has been obtained for the new expansion on the Rand since South Africa passed off the gold standard, constitute ample proof of the value of the 'group' system. The mean annual yield on the total capital engaged on the Rand has been estimated as only 4.1 per cent. by S. H. Frankel, who attributes this low rate to the large-scale nature of the investment (between 3 and 4 million pounds is required for opening up a new mine to-day) and the long period of development during which no return to capital accrues. The calculation, however, is based upon all capital invested, including the amount sunk in speculations which have failed; the return on the capital invested in existing mining companies is considerably higher, the average for 1935 being 24.5 per cent., or 39.2 per cent. on the issued capital of producing and dividend-paying concerns.

Although over 95 per cent. of the gold won in the Union has come from the Witwatersrand, there are important fields in other Transvaal districts where the first discoveries of the metal in the country were made. The richest are situated in the Eastern Transvaal near Barberton, Lydenburg, and Pilgrim's Rest, and in the north-east at Pietersburg and Letaba. A considerable increase in mining activities has taken place in these areas following the Union's departure from the gold standard. Within the last few years important discoveries have been made in hitherto unexplored areas lying to the south-west of the Witwatersrand, and these bid fair to become large contributors to the gold production of South Africa in the near future.

Base Minerals. As has been shown, gold has an exceptional position in 'marketability'. In regard to other metals South Africa has proved to be less favourably placed, since they possess no advan-

¹ S. H. Frankel, *op. cit.*, chap. iii, p. 89.

tage over those produced in Europe or America under a highly industrialized system. Many of the base metals and minerals can only be processed or utilized overseas and the cost of transport renders exploitation unremunerative. Coal, however, stands in a special category as a source of power. As far back as 1852 the Cape Government had offered a prize for the discovery of coal, but though a deposit was found in 1859 its poor quality led to its being replaced by coal from the Transvaal or Natal. There is evidence that natives had used outcrop coal in Natal in pre-European days, and the early trekkers of 1839 came on its traces; its first commercial use in Natal dates from 1852, but serious development was only possible in 1881 on the arrival of the railway. In the Transvaal also coal mining, which began at Bethal in 1868, was not developed until the gold mines created a demand for cheap fuel and the railways provided the means for its transport. South Africa now possesses an abundant supply of coal, worked by native labour at comparatively low cost, and situated near the mining centres; without the assistance of this cheap supply the continued expansion of the gold and diamond industries would have been impossible. In 1934 the average pithead price was 4s. 11d. per short ton, against 11s. 6d. in the United Kingdom. Output increased from 3,673,000 tons in 1904 to 15,996,376 tons in 1936, and is sufficient not only for the country's own needs, but also for bunkering and export to East Africa, India, Ceylon, and South America. All the coal mines are, however, situated more than 200 miles from the coast, and the cost of railage is a severe handicap in competing with coal from other countries. In the Transvaal a system of 'rationalization' by the Transvaal Coal Owners' Association has had advantages similar to those which resulted from the introduction of the 'group' system in the gold mines on the Rand.¹

Since their discovery in 1922 the manganese deposits of Postmasburg have been found to extend along a strike of over 40 miles. During 1933 and 1934 the content of metallic manganese averaged 49.6 per cent. Production rose from 10,306 short tons during 1929 to 283,779 short tons for 1936. Up to recent years,

¹ L. C. A. Knowles and C. M. Knowles, *Economic Development of the Overseas Empire*, 1936, vol. iii, p. 234.

relatively less attention has been paid to the base minerals, though rich deposits are known to exist, but the Union Government has recognized that its mineral development is one-sided and has begun a systematic study of the resources of the base minerals. In 1933 it appointed a committee to ensure the co-operation of the Mines and Geological Departments, and it has also assisted in the establishment of a mineral research laboratory at the Witwatersrand University. A Small Mines Assistance Committee does important work in financing the development of ore in small mines, and has established a fuel research committee. Another important development is the erection of a large iron and steel plant at Pretoria as a government concern, the Iron and Steel Industrial Corporation, which obtains its iron ore from two mines, one in the Rustenburg District and the other at Pretoria.¹

In South-West Africa, gold, which is of the alluvial type, was discovered in 1924; it is mainly in the lands of small holders, who produced 3,059 standard gold ounces in 1937. Its largest production of other minerals is in copper, exported to the value of £186,601 in 1937, and vanadium, exported to the value of £199,017. There is also some export of tin. The largest copper mine, the Tsumeb, was under water for five years but was dewatered in 1936.

(b) *Bechuanaland Protectorate, Swaziland, Basutoland*

In Bechuanaland gold mining has been carried on in the Tati District; in 1932 2,247 fine oz. was produced, value £9,443, and in 1936 16,723 fine oz., value £117,061.

Mining in Swaziland is confined to alluvial tin, in the vicinity of Mbabane, and gold. Large deposits of coal exist in the low veld, but beyond prospecting nothing has been done to exploit these. In the north-west of the territory a deposit of asbestos was discovered, and the rights have been acquired by a private company.

In 1932, 84 tons of cassiterite tin was mined, value £11,497, and 315 oz. of gold, value £1,542; in 1936 183 tons of tin was mined, value £36,351, and 276 oz. gold, value £1,938.

In Basutoland the chiefs and people are adverse from prospecting of any kind and no development has taken place.

¹ See below, p. 1536.

(c) Southern Rhodesia

Gold. The gold discoveries in South Africa stimulated prospecting farther north in Bechuanaland and Matabeleland. The grant by Lobengula of the Rudd Concession, which was afterwards acquired by the British South Africa Company, gave the latter the sole control of all minerals in his kingdom, but the Company proceeded in the first instance by the grant of licences to prospectors. The pioneers who constituted the first expedition to Mashonaland had been promised fifteen gold claims apiece, and were soon engaged in prospecting near the ancient workings, without, however, finding a gold field of any considerable importance. The size of the producing unit in mining, as in other industries, tends towards an economic level determined by the richness and accessibility of resources, conditions which, in Southern Rhodesia, have promoted an exceptionally large number of small enterprises. The gold-bearing schist belts give rise to most of the richest agricultural soil, so that the mining districts are also best suited for farming, and the miner thus has the advantage of having food supplies near at hand. Further, though the country is sparsely forested, timber is everywhere sufficient for fuel and other requirements. If the territory had been as bare as parts of the Union, the small owner would have suffered a severe handicap, and only deposits large enough to warrant railway branch lines could have been worked. Even under these conditions, several potentially good districts in the south-east and north-west of Mashonaland have been neglected owing to their remoteness from the railways. Gold occurs in a variety of conditions, including rubble and surface deposits, quartz reefs, and replacement bodies. In general the deposits are widely scattered, and many are small and easily worked, conditions that favour the individual miner but do not attract the large corporation. In the early days prospectors concentrated on the search for old workings; the small miner also tended to pass from one property to another after taking out the most accessible ore, a practice that did much to hamper progress. Development was also retarded by a shortage of native labour,¹ which could not be overcome by the use of

¹ See Chap. XI, p. 653.

labour-saving devices since the mines were not large enough to warrant the expenditure, and by the lack of capital for the purchase of plant.

The first mining laws stipulated that a prospect could be worked for profit only by a limited liability company in which 50 per cent. of the vendor interest was allotted to the Chartered Company as owner of mineral rights, though in practice the Company took only 30 per cent. A large number of companies was floated, many of which were primarily speculative, making actual production a secondary consideration. The poor results attained led to a general pessimism regarding the industry. In 1903 the Chartered Company allowed small miners and syndicates to work for profit, and finally in 1907 royalties were substituted for a share basis in all new claims. The number of producers steadily increased, and the value of the gold output rose from less than £1,000,000 in 1904 to approximately £3,900,000 in 1916. There succeeded a period in which many of the smaller mines fell out of production, and in 1931 the output fell to the 1907 level. The increase in the price of gold brought about a rapid growth in the number of small properties from 286 in 1930 to 1,440 in 1937, when they contributed 28·7 per cent. of the total output of £5,656,693, the remainder coming from 32 mines producing more than 1,000 oz. each.¹

The mining laws have been framed with the purpose of encouraging the individual worker, who was described in 1932 by the Secretary for Mines as 'the saviour of the mining industry'. In 1933 the state bought the British South Africa Company's mineral rights. Exceptional assistance has been given to the smaller worker in the way of loans, free testing by the metallurgical laboratory, and free advice from the Government Mines and Geological Departments. The state bears the cost of drilling on approved properties; the cost is charged to the claim, but the owner may free himself by abandoning the property. Nevertheless, there have been periods when the small worker has fallen into straits which called for state aid to enable him to continue operations. The activities of these

¹ Third (Triennial) Empire Mining and Metallurgical Congress, 1930. *Mining Journal Centenary Number*, May 1935. *Report of the Secretary, Department of Mines and Public Works, on Mines, for 1934*, C.S.R. 15, 1935.

small enterprises have led to the exploitation of resources that otherwise might have been neglected, but it may be said with equal truth that the mainstay of the industry has been a group of large mines, some ten in number, which until 1934 produced over 50 per cent. of the output. A tendency towards the policy of encouraging the larger organization was apparent in 1930, when the British South Africa Company, which at that time owned the mineral rights, granted to the Victoria Prospecting Company an exclusive licence over some 9,000 square miles; a proposal to grant a concession over another area was withdrawn owing to the opposition of small workers. The increased price of gold has lately induced mining companies domiciled outside Rhodesia to devote capital to the testing and acquisition of small properties for working under the 'group' system.

Base Minerals. In Southern Rhodesia it is estimated that up to the end of 1936 the total value of mineral products was £131,500,000, of which gold contributed 76·2 per cent., asbestos 9·5 per cent., chrome ore 5·5 per cent., coal 5·5 per cent., and copper 2·2 per cent. Asbestos mining began in 1908 with 55 tons and reached its peak in 1929 with an output of 42,634 tons, valued at £1,186,000. As the Russian output is unknown, Southern Rhodesia is believed to be the second producing country in the world; owing, however, to distance from the market, only the best grades of fibre can be exported with profit. Extensive chrome ore deposits are worked at Selukwe and in the Districts of Lomagundi and Victoria. Production reached 293,116 tons in 1929, but fell to 17,298 tons in 1932, since when under the influence of trade recovery it has risen to 202,159 tons in 1936. Southern Rhodesia is the leading world producer of chrome ore, and strong financial interests are in charge of the major sources of supply; but the industry is handicapped by a number of small properties that cannot guarantee a regular monthly output.

Coal deposits have been found both in the Zambesi valley and the Limpopo basin, but mining operations are restricted to the Wankie fields, 212 miles north-west of Bulawayo, which enjoy a position of advantage for export to the Northern Rhodesia copper-belt and the Congo. The Wankie Company, in which the British South Africa Company has a share interest, holds mining rights

over an area of 400 square miles, estimated to contain not less than 6,000,000,000 tons of coal. The deposits are easily worked and the coal is of good quality, yet the average annual quantity raised during the period 1904-30 was less than 500,000 tons. It reached its peak in 1928 with 1,206,800 tons and fell to 482,925 tons in 1934, the output in 1936 being 777,221 tons. The expansion of the Wankie field is handicapped by the fact that, apart from the railways, the only consumers are the copper mines in the north. The fall in output is attributable to the loss of part of the demand from Katanga, which has developed its own hydro-electric installations and now imports charcoal from Belgium. It also draws some coal supplies from the Luena Collieries, south of Bukama in the Congo, where about 120,000 tons are raised yearly.

(d) *Northern Rhodesia*

Northern Rhodesia has had a different history of mineral development, for gold has been less in evidence, and the British South Africa Company, which retained the mineral rights on the termination of the Charter, has found that the development of the copper ores could only be secured by the co-operation of powerful financial organizations. By 1903 a few of the copper deposits had already been located, and attempts were made to work these ores almost immediately, but development could not advance until the railway had reached the Congo border in 1909. The deposits often occur at considerable depth, and the presence of a thick laterite covering necessitated costly exploratory work before the value of the ore could be proved. The earlier finds were of oxidized ores, averaging only 3 to 5 per cent. copper, against the 7 per cent. copper of ore in the Belgian Katanga, and attention was for many years diverted to the search for oxidized ores of a higher grade. On these lines no significant progress was made until 1923, when development interests were consolidated in the hands of a small number of powerful companies, who held their rights on condition that they expended a certain minimum amount on the work. The Rhodesian-Congo Border Concessions received rights over 52,000 square miles, and subsequently the Rhokana Corporation, the Luangwa Concessions, and the Rhodesia Mineral Concession

acquired concessions over an aggregate of 206,000 square miles. At the end of 1931 almost half this area had been systematically prospected, over sixty geologists being engaged on the work.

As a result of this scientific exploration, unique in the British areas of Africa, it was found that the deposits entered a sulphide zone at a depth of about 100 feet. This discovery changed the outlook for the industry. Sulphide ores of 3 to 5 per cent. of copper were profitable, whereas oxidized ores of similar grade were almost valueless. By 1930 the copperbelt was in the midst of an extensive development boom, and though in that year the market collapsed, leaving only the Roan Antelope and Nkana Mines active at the end of 1931, nevertheless the Rhodesian mines, working rich and easily mined deposits, or sulphide ores that can be treated by simpler methods than most oxidized ore, have been able to prove themselves among the lowest-cost producers of copper in the world. Their position enabled them to take immediate advantage of the increase in consumption that began in 1933, and mines that closed during the depression have been reopened. During 1935 and 1936 minerals to the value of £5,229,970 and £6,375,929 were produced in Northern Rhodesia. Of a total mineral production of £30,944,989 in the years 1906 to 1936 inclusive, copper constituted 73·17 per cent., lead 9·95 per cent., zinc 8·37 per cent., vanadium 4·5 per cent., cobalt 2·69 per cent., gold 0·9 per cent., and the balance of 0·42 per cent. comprised silver, manganese, mica, tin, and bismuth. Development expenditure had amounted to £17,000,000 by June 1932. The Nkana Mine is believed to be the largest producer of cobalt in the world, and zinc is produced on a large scale at Broken Hill, where it occurs jointly with lead and vanadium. The geological survey undertaken by the concession companies has lately indicated the existence of gold in Northern Rhodesia, but the value of the deposit has not yet been explored.

(e) *Nyasaland and Tanganyika*

About fifteen years ago the director of the geological survey of Nyasaland estimated the presence of 22,000,000 tons of bauxite on the Malanje plateau of Nyasaland, and analyses suggest that

it would be suitable for the manufacture of aluminium. However, such mineral deposits as may exist in Nyasaland have not yet been exploited. The British South Africa Company and the British Central Africa Company own the rights in about two-fifths of the territory, but systematic prospecting seems to have been delayed pending the negotiations, now concluded, regarding the surface rights in the North Nyasa District.¹

In Tanganyika the German administration gave definite encouragement to prospecting, which, though hampered by transport difficulties and the disturbance associated with conquest, located gold, diamonds, copper, iron, coal, and mica deposits. Gold was mined to a small extent near Mwanza and Sekenke, the value of the output from the latter field exceeding £200,000 prior to 1914, after which it remained inactive until 1929. It is still the most productive mine in the territory. Prospectors discovered and began work in the Lupa goldfields in 1922, and later found diamonds, tin ore, and a number of other gold reefs. Since 1926 the Geological Survey, the institution of which was unduly delayed, and the creation of a Mines Department have greatly facilitated exploratory work. These departments are now combined, with others, in the Department of Lands and Mines. Production suffered at first from want of capital, and experts sent out by important mining companies to the Lupa were discouraged by the lack of communications; as a result the development of the Lupa was left to small prospectors, belonging to a great variety of nationalities. Many of them were farmers from East and South Africa who had suffered from the depression in prices.

The increase in the price of gold assisted operations in Tanganyika by enabling the low-grade ore to be worked at a profit in spite of transport and labour difficulties, and whereas at the beginning of 1933 scarcely a company with any appreciable capital operated on gold interests, a year later five or six major organizations and an equal number of smaller syndicates were opening up and testing prospects, and production grew rapidly in the Musoma and Lupa fields. The latter is still predominantly alluvial, worked largely by small undertakings; but mines such as Buhemba and Mara in Musoma, Saza in the Southern

¹ *Report of the Commission on Emigrant Labour, 1935, para. 128.*

Highlands, and Sekenke in Nkalama are greatly extending the production of reef gold. The output of placer gold, which was nearly 100,000 oz. during 1927-34, was ten times greater than the amount won from reef deposits; of the total gold produced in 1936, 42 per cent. was from reefs, and a further steady increase from this source is said to be expected. Water is plentiful in the Lupa only in the wet season, and the cost of well-sinking is beyond the means of most individual miners, while at greater depths on reef diggings a sulphide zone is reached, which increases the difficulty of extraction. A comprehensive form of assistance for the small worker is now under consideration, whereby small mines of proved promise may be able to obtain metallurgical advice and financial assistance to ensure efficient equipment and production. But the stage is being reached where exploitation of larger-scale recurrences is passing into the hands of organizations with the ability to prove the value of resources by scientific research and development beneath the surface. The value of such research is shown by recent discoveries at Geita, south of Lake Victoria, where important gold-bearing reefs have been indicated. The value of gold produced in the territory, which was £38,630 in 1929, increased to £490,490 in 1936, and in the same year the value of tin produced was £41,784. Coal and iron deposits are believed to be extensive in the south-west, but conditions are unfavourable for their development.

(f) *Kenya*

The initial development in Kenya was largely the work of individual prospectors. Reef gold was mined in South Kavirondo several years before the discovery of rich alluvial deposits in the Kakamega District of North Kavirondo in 1931. The activity of prospectors revealed the existence of payable gold in a number of streams, and subsequently the reefs from which the alluvial metal had been derived were located. Farmers and others affected by the depression turned to the alluvial deposits, which are still being worked, but the industry can be stabilized only by the exploitation of the reefs. This work is now being undertaken by syndicates and companies holding mining titles over large areas of low-grade alluvial, and equipped for production at a lower cost than the

small worker can achieve. The transitional period has seen considerable public interest in the discussion of the respective merits of the individual prospector and the larger financial organization. When Tanganyika Concessions in 1932 applied for a two-year exclusive prospecting licence over 5,900 square miles in Kavirondo and agreed to spend at least £20,000 on exploration during the period, the settlers claimed that individual prospectors, who had by their own efforts discovered the Kakamega fields, would make a more intensive search than a company, which should in their opinion come in after prospectors had found workable deposits.

Sir A. Kitson,¹ in reporting on this issue, advised against the concession to a company of the only areas in which persons with limited means could extract gold at low cost without metallurgical treatment. He distinguished the position of such areas from those containing base metals. In the latter case, where the ores occur under conditions requiring expensive plant for mining, separation, and smelting, strong companies are necessary; similarly, capital beyond individual resources is needed to work reef gold which is associated with one of the base metals, when expensive treatment may be necessary. The strong company can then step in and buy the mine from the discoverer without having to undertake the preliminary prospection. In areas such as Kakamega, however, the smaller prospector for gold had, in his opinion, a legitimate field for his activity. The final decision was in the nature of a compromise: the field was divided into five areas: two, aggregating 1,490 square miles out of 5,900, were thrown open to small companies and private prospectors, and the remaining three were reserved for leasing under exclusive licences to large companies, among which Tanganyika Concessions received one area of 1,550 square miles. Concessions are given on condition that an aerial survey be made and a copy of the map, together with the results of the work done, be sent to the Mines Department. The output of unrefined gold from Kenya increased from 845 oz. in 1929 to 48,635 oz. in 1936. A considerable quantity of sodium carbonate is produced from Lake Magadi, the export for 1936 amounting to 46,549 tons.

¹ Sir A. Kitson, *Geographical Reconnaissances in Kavirondo and other districts of Kenya*.

(g) Uganda

In Uganda before the War such little prospecting as was carried on met with no success, and in subsequent years mining has owed much of its development to the researches of the government Geological Survey. The discovery of gold at Kakamega, the announcement by the Survey of finds in the Eastern and Western Provinces, and the rising price of gold led to considerable activity, and mineral exports increased in value from £44,517 in 1929 to £184,312 in 1936, of which tin ore accounted for £58,844, gold for £92,792, and tantalite for the remainder. No reef gold of any significance has yet been mined, but important copper deposits are in the course of investigation at Kilembe. The tin has been produced almost entirely from lodes or detritus, and its discovery illustrates the fact, noticeable in other areas also, that discoveries of metals such as tin are frequently made in areas previously rejected by holders of large exclusive prospecting licences. Tin ore was first located in 1924; production began in 1927 with 114 tons, and up to the end of June 1937, more than 3,522 tons had been recovered. An interesting example of mineral production which remains under native control comes from Western Uganda. The extraction of salt from the crater lake of Katwe is a traditional native industry, and remains under the control of the native government of Toro. The 1934 production from Katwe and the near-by lake at Kasenyi totalled 2,206 tons of salt and gave rise to a considerable trade in Western Uganda and the adjacent parts of the Belgian Congo.¹

(h) Nigeria

The most important metalliferous mineral yet exploited in Nigeria is cassiterite, which the Hausa have mined and smelted within a hundred miles of Kano from very early times; but finding the local supplies insufficient they took control of the mines worked by pagan tribes on the Bauchi plateau farther south. In 1884 the Niger Company realized that the metal used for tinning the natives' brass-ware was not brought across the desert, as had been sup-

¹ H. B. Thomas and R. Scott, *Uganda*, 1935, pp. 220, 285; 1936 production was 2,560 long tons.

posed, but came from the local interior, and an expedition was sent to Badika, the market for tin, in an attempt to locate the field. A force sent in 1902 to subdue the Emir of Bauchi obtained a sample of tin from the Delimi river near Naraguta, following which a prospecting party was sent out later in the year. Large prospecting areas were taken up by different companies under licence from the Niger Company, and tin-mining quickly developed into an important industry in the Provinces of Bauchi, Zaria, Kano, and Ilorin; the richest of the mines are situated on the Bauchi plateau, an area of about 2,000 square miles. Here deposits are alluvial, and the ore is won by a variety of means, ranging from manual washing to steam shovels or bucket dredges with a dressing plant attached. During a period of boom, expensive machinery was installed, but much of this is now idle, and hand-work is considered the best method for excavating the tin-bearing earth. Mining is also extensively carried on by natives under headmen, working as 'tributers' for individual Europeans and companies. The product is a concentrate of tin oxide with a metal equivalent of at least 70 per cent., and is for smelting exported in this form.

Extensive developments began in 1910, when companies were floated to work areas acquired from the Niger Company, but lack of communications held up expansion until the railway was brought to Naraguta in 1914, and to Bukuru in the following year. The War interrupted activities, while subsequently the international tin restriction agreement, first adopted voluntarily by the producers and then made compulsory by government, confined production to existing mines. The peak output of 15,335 tons in 1929 made Nigeria the fourth tin-producing area of the world; in 1933, the restriction scheme reduced production to 4,956 tons; in 1936, at 13,432 tons it represented the second largest output in the British Empire, with a value of £2,011,000.

The second important mineral of Nigeria is gold, which has been mined by a few small companies, but chiefly by individuals, since 1914, but owing to lack of capital, development is still confined to the alluvial stage. The Associated Tin Mines of Nigeria investigated superficial deposits of gold in the Niger Province during 1931, but, though the results were promising, the low-grade character of the ore has not attracted large financial groups. It has

been contended that the mining laws are unfavourable to enterprise, in that leases are too restricted in size, in view of the large outlay which is required on preliminary work before production can begin.¹ The gold output in 1936 was 33,364 oz., valued at £233,780. The coal output is also of some dimensions. The colliery situated at Enugu, 151 miles from Port Harcourt, began to yield coal in 1915, and is owned and worked by the government. It is capable of producing 400,000 tons a year, which exceeds the local demand; further prospecting for coal is therefore prohibited. The mine supplies the railway both in Nigeria and the Gold Coast, and ships that call at Port Harcourt. Operating costs are small, but owing to high transport charges the price is 14s. at the port and 30s. at Lagos, where Welsh coal is actually cheaper, and in order to retain the Gold Coast trade haulage charges have been so adjusted that Nigerian coal is supplied to the railways at rates which will prevent competition from Lagos. Nigeria exported 511 tons of columbite in 1936 and is said to be the world's source of supply.

(i) *The Gold Coast*

On the Gold Coast gold, though its existence was long known to Europeans, was, apart from sporadic efforts by the Portuguese, left in the hands of natives until the late seventies. Samples of gold-bearing quartz from the Gold Coast were brought to Europe after the Ashanti War of 1873, and a prospecting company was formed. In 1877 the Frenchman Bonnat, who had been imprisoned by the Ashanti, disclosed the existence of the Tarkwa mines, then being worked by some 6,000 natives.² Their workings were left undisturbed and the surrounding lands were leased to a French company, which eventually took over the native reservation when lack of water caused its abandonment.³ Activities then greatly increased; numerous concessions were obtained, old native workings were explored to greater depths, and individuals and companies prospected for minerals in new ground; but progress was slow, and output did not exceed 18,000 fine ounces a year until the boom of 1900-2. Though operations at first centred on the older

³ O. A. L. Whitelaw, 'Drilling on the Gold Coast', *Institution of Petroleum Technologists*, vol. xv, 1929.

native workings, the surveys made by the Geological Department, and the systematic work carried out of late years by mining companies, have shown promising prospects at many places where no evidence existed of native activity.

Gold occurs in alluvial deposits in quartz reefs, and in sedimentary beds of the 'banket' type similar to the deposits of the Rand. The main gold-mining centres are Obuasi, said to be one of the richest mines of its size in the world; Tarkwa, where 'banket' is being worked and developed on a considerable scale, and Prestea, Bibiani, Marlu, and Kanongo. Two dredges are in operation on the Tano river and others are to work on the flats of the Ankobra river. Only the best parts of mines have so far been thoroughly exploited, and it would appear that with improvement in operating methods considerable further developments may be looked for in the future. Production in fine ounces grew from 246,075 in 1930-1 to 428,144, valued at £1,818,756, in 1936. The export of manganese is now of growing importance, having amounted to 411,024 dry tons valued at £612,930 in 1936. Diamonds are dealt with separately on pages 1509-12.

(j) *Sierra Leone*

In Sierra Leone minerals of economic value were unknown until government geologists discovered important deposits of gold, diamond, platinum, and iron ore in the years 1926-31. The production of gold is confined to alluvial deposits, and is carried on by a number of comparatively small enterprises, one concern alone being responsible for over a quarter of the output. There has been considerable development in the production of iron ore from the Marampa mines, and prospecting is being carried out in connexion with haematite deposits in the Simbili and Numbara hills. In 1936 mineral production was 40,764 ounces of gold, 484 ounces of platinum, and 566,595 tons of iron ore; the total value, including diamonds, being £1,249,695.¹

(k) *The French Territories*

In French West Africa policy was for some time directed to the development of agricultural rather than of mineral products.

¹ See below, p. 1514.

There was already an active native gold-mining industry, and the customary rights of the community engaged in it were respected, considerable areas being excluded from prospecting by Europeans, notably in Siguiri, the Canton of Boauri, and a large part of Sieke.¹ European enterprise was slow to give attention to mineral exploitation. In the French Sudan during the ten years between 1902 and 1912 forty-three *permis d'exploitation*, covering an area of 68,600 hectares, were issued; and in Guinea in the period 1901-8 395 permits were granted over an area of 2,450,000 hectares, of which more than a fourth was in the *cercle* of Siguiri. Many holders of permits, however, did no prospecting, and only one company, the *Société des Mines de Falémé-Gambia*, which operates placer-gold dredging on the Falémé river on the Sudan-Senegal frontier, reached the producing stage. Development has been equally slow in the French Cameroons, which has only of recent years attracted the attention of prospecting companies. In French Equatorial Africa mineral rights were expressly excluded from the large land and rubber concessions granted to Europeans; prospecting did not begin until 1911, and little exploitation took place until 1929.²

The gold premium has, however, stimulated activity in recent years; the number of prospecting licences in French West Africa increased considerably between 1933 and 1934,³ and the exports of gold from the federation, the largest producer in the French Empire, were 66 kilograms in 1929, 2,066 in 1932, and 3,039 in 1934, the value of the total output for the five years before 1934 amounting to over 150,000,000 francs. But only a small proportion (in 1934 just over 4 per cent.) is won by Europeans, mainly by the dredging company on the river Falémé, which produces about 100 kilograms a year. The more important centres of native mining are the District of Siguiri, in the north-east of Guinea, which provided 72 per cent. of the exports, the region of Satadougou, and parts of the Ivory Coast. French Equatorial Africa, where gold mining began only in 1929, produced 806 kilograms in 1933. In the Cameroons prospecting is now being actively pursued along the confines of the

³ *Annuaire statistique de l'Afrique occidentale française*, 1933-4.

Ubangi-Shari, whence a small shipment of gold was made in 1934, production rising from 13 kilograms in 1934 to 88 in 1935.

The statistics of exports from French West Africa do not reflect the amount actually produced, for much of the native gold coming from Senegal and the Sudan had been hoarded and was released during the depression. The total production of new gold in French West Africa was estimated to be 1,608 kilograms in 1933, against 2,138 kilograms exported. The natives usually work alluvial ground only, although lodes have been developed to a limited depth in the Ivory Coast, shafts in some places being sunk to a depth of 15 metres. Throughout, the technique employed is crude and wasteful. For nearly six months of the year during the wet season the mines are unworkable; the tunnels frequently collapse owing to weak supports; and the method of extraction results in the loss of a considerable proportion of auriferous gravel and gold. Despite these difficulties, some 20,000 native miners are at work in Guinea, and a population of 60,000 is dependent on the industry. The Mines Department has been instructing the workers of the Ivory Coast in the use of sluices and other improved methods of production. French writers have pointed to the anomaly that where natives can win a substantial production of gold, European enterprise has so far achieved little; in their view prospectors have assumed that the only sources of gold are those already being worked by natives, though it has been proved that adequate deposits occur where no native workings exist.¹ It is perhaps true that the Europeans engaged in prospecting have allowed themselves to be unduly deterred by the previous failure of enterprises undertaken without systematic investigation or adequate capital. The government itself has come under some reproach for lack of interest in mineral development;² only of late years has it undertaken a systematic geological survey; now, however, it is also conducting a special survey of the central Niger area through the *Office du Niger*.³ The latter has already indicated both gold and mineral deposits.

(1) The Belgian Congo

The Belgian Congo presents, on the whole, a picture of greater activity than the French territories. Only a minor part of the development has been due to the prospector or small enterprise. The state from the first sought to find in export production a means of increasing its own resources in order to meet the heavy cost of communications and administrative development in a country of low taxable capacity, and the knowledge that copper occurred in the Katanga accentuated its anxiety to conserve a right over this area, at a time when the British South Africa Company was seeking agreements which would extend its control northwards. In promoting mineral development the government has availed itself largely of the support afforded by the financial interests united in the *Société Générale de Belgique*. A geological survey was initiated in 1891 in Katanga, the copper deposits of which formed a valuable first line of development. Here at least 150 deposits of various minerals have been located in a belt 200 miles long and 15 to 60 miles wide; the proved copper reserves in this area and in the adjoining field of Northern Rhodesia together are believed to form over one-third of the world's known resources. The majority of the copper ore-bodies are composed of oxide copper minerals which at comparatively shallow depths pass into disseminated copper sulphides so low in grade that they cannot be mined profitably. There are exceptions of which the Kipushi Mine is the most notable; here bodies of copper sulphides average 15 to 20 per cent. of copper and about 12 ounces of silver per ton. Drilling has disclosed copper deposits at Musoshi and Tshinsenda similar in type to those of Northern Rhodesia, but less regular in their mode of occurrence and of lower average copper content. The metal occurs in large hills standing above the level of the country, and outcrops are comparatively frequent, which accounts for the speed with which the Katanga deposits were exploited in comparison with those of Rhodesia.

In 1891 an exclusive right to minerals in this area was given to the *Compagnie du Katanga*, which in 1900 created a development company, the *Comité Spécial du Katanga*. This company, in turn, conceded a prospecting monopoly to an English group, Tanganyika

Concessions, formed by Sir Robert Williams, whose company was able to provide the technical knowledge which the Belgians at that time lacked. Eventually, the sole right of exploiting the mineral resources of Katanga, extending over an area of 15,000 square kilometres, was assigned until 1990 to the *Union Minière du Haut Katanga*, representing jointly the Tanganyika Concessions, the *Comité Spécial du Katanga*, and the *Société Générale de Belgique*. Apart from the area in which it has exclusive rights over copper mines, the *Union Minière* holds a concession for working tin deposits over a total of 12,000 square kilometres.

Active development of the copper deposits was delayed until the railway, which reached Élisabethville in 1910, provided the mines with an outlet for their products to Beira, and enabled coal to be brought from Wankie and stores from the port and from South Africa. The *Union Minière* began producing in 1911, when the output was 1,000 metric tons. The War stimulated activities, and in 1918 over 20,000 tons was produced. The rate of expansion was steadily maintained, except during the economic depression of 1931-3, and in 1936 the output was 97,500 tons, about 10 per cent. less than in the previous year. In addition to copper, the rich uranium ore at Chinkolobwe, 110 miles from Élisabethville, is one of the chief sources of the world's supply of radium.¹ The *Union Minière* affords a conspicuous example of the manner in which a large monopoly right can be used for the scientific exploitation of mineral resources. It has conducted a careful geological and topographical survey of the area it holds, and has devoted great care to the welfare conditions of its labour.²

The second line of development in the Congo has been gold, the highest production of which is at the Kilo-Moto Mines, some of which were discovered in 1895 by M. Henry and others in 1903 by Australian prospectors in the employ of the Free State. The mines began production in 1905. Ten years after annexation the Congo Government decided to open up new deposits and generally to 'industrialize' the mines. It decided that the administration itself was not equipped to carry out a programme of this nature, and for the purpose created a special organization, the *Régie Industrielle*

¹ Important uranium deposits have also been found at the Great Bear Lake in Canada.

² See Chap. XI, p. 681.

des Mines de Kilo-Moto. In 1926 the *Régie*, in its turn, was converted into the *Société des Mines d'Or de Kilo-Moto*, a joint stock company with a nominal capital of 230,000,000 francs consisting of 200,000 shares of 1,000 francs each, and 60,000 preference shares of 500 francs. All the former and two-thirds of the preference shares were allotted to the state. The remaining 10,000,000 francs constituted liquid capital, subscribed mainly by banking houses. Fixed dividends are paid to private shareholders, and the balance of net profits is paid into state revenue. The company successfully works deposits mainly alluvial, but of unusually low-grade character.

An associated undertaking, the *Compagnie des Chemins de Fer du Congo Supérieur aux Grands Lacs Africains*, holds exclusive mineral rights over 8,000,000 hectares in other parts of the territory. It threw open to public prospecting a zone of 200 kilometres on the right bank of the Congo and ceded an area to the *Comité National du Kivu*, which also has rights over all mines not previously conceded, in a belt 100 kilometres wide extending from Lake Tanganyika to the south of Lake Albert. Mineral products contributed 70·5 per cent. of the total value of exports from the Congo in 1931; in 1933 the proportion had declined to 54·3 per cent., and in 1935 it was 62·4 per cent., the decrease from 1931 being due mainly to the contraction of the market for copper and diamonds. In 1936 the value of minerals exported was 913,000,000 francs, of which gold contributed 38·8 per cent., copper 34 per cent., tin 15·8 per cent., and precious stones 11·4 per cent.

(m) *Portuguese East Africa*

Portuguese East Africa produces a small amount of gold, amounting to 10,195 oz. valued at £42,829 in 1934, mainly in Manica under the administration of the Moçambique Company. Coal deposits occur in several areas between Tete and the Nyasaland border, and in the Zambesi basin opposite Tete. In the latter region a Belgian company is producing about 10,000 tons of coal a year for plantations lower down the river. It is understood that the Portuguese Government has sanctioned the building of a railway to connect the coal field with the main line from Beira to Nyasaland, which, when completed, will enable output to be considerably increased.

III. DEVELOPMENT OF THE DIAMOND INDUSTRY

(a) South Africa

For the reasons stated on page 1486 diamonds have been reserved for separate treatment. The diamond has borne so large a part in African history as to justify a study of the industry in some detail. The early discoveries in the Cape and Free State resulted from a sporadic picking over of gravel along river beds. At first the Kimberley 'pipes' were worked under conditions suited to alluvial diggings, in small and much subdivided claims, but these methods became impossible as the deposits were followed deeper into the earth and, in addition, the unrestricted sales soon began to depress market values. It became clear that without capital and an elaborate organization neither subterranean mining nor the control of production was possible; the claims were therefore consolidated under joint stock companies, which were then amalgamated, until by 1892 De Beers controlled all the mines of Kimberley. Rhodes, aiming further at a monopoly over all diamond mines in the sub-continent, acquired rights in every locality where a discovery threatened the interest of De Beers. When he secured the Charter for the British South Africa Company he obtained for De Beers all diamond rights in the Rhodesias and part of Bechuanaland. The company at first underestimated the richness of the Premier Mine at Pretoria, the biggest find since the opening of the Kimberley group, but it eventually bought a controlling interest in the property.

The products of the alluvial diggings did not at first threaten the prosperity of the mines. From the beginning the alluvial diggings scattered along the Vaal river in Griqualand West and spreading up to Klerksdorp in the Transvaal had provided employment for numerous small companies and individuals, many of whom were people of rural origin unable to make a living on the farms. Diggers could obtain a licence on almost nominal terms. Whenever a new field was proclaimed a 'rush' ensued, but only a few were successful and the rest drifted back to the farms and towns. The bulk of the diggers lived in extreme poverty; in 1929 about 45 per cent. of those in the Transvaal were stated

to be living on an average of £5 a month or less.¹ Until after the War the output of alluvial stones did not exceed 10 per cent. of the total production for the Union, and the mines found no difficulty in adjusting their production to this supply. In 1925, as a result of the first scientific attempt to trace the origin of the Vaal alluvial diamonds, rich deposits were located in the Lichtenburg and Rustenburg Districts of the Transvaal. In the following year government, sympathetic to the diggers, threw open the Lichtenburg fields, and at the end of the year 80,000 Europeans and over 100,000 other persons were living on the diggings. Between 1925 and 1927 the production of alluvial stones rose from 239,257 to 2,318,407 carats, while the average value per carat, which normally was three times that of mine stones, fell from £7 19s. 5d. to £2 13s. 6d. In the same period the mines' production remained roughly constant at 2,250,000 carats, valued at £2 18s. per carat. For the first time the production and value of mine and alluvial stones were now approximately the same. The controlling companies were forced to buy up large quantities of alluvial diamonds to maintain prices.

The next threat to the stability of the industry came from Namaqualand, where the existence of diamonds, though known for many years, had not attracted attention until Dr. Merensky in 1925-7 showed that diamantiferous ground extended for over 100 miles southward from the Orange river mouth and northwards into South-West Africa. Free production in this rich field, where diamonds could be extracted at the cost of 1 per cent. of their value, would have destroyed the market. In 1927 the Precious Stones Act was passed, and the government prohibited prospecting in the area, except for 100 discoverers' claims allocated to the Merensky Syndicate near Alexander Bay, and the farm Klein-zee at Buffelsrivier mouth operated by the Cape Coast Exploration Company. Subsequently, a valuable area of twenty square miles was reserved as government diggings. The state itself thus acquired a direct interest as a producer and marketer of diamonds.

At the same time the Act also modified the previous policy

¹ *Report of the Carnegie Commission on the Poor White Problem in South Africa*, 1932, part i, p. 153.

in regard to the alluvial diggers in the Union. It preserves to private landowners exclusive prospecting rights on their land, but enables regulations to be made which, while allowing for the grant of permits to diggers, practically excludes companies and syndicates. A limit may be fixed to the total amount of alluvial production, and a severe restriction of the number of diggers' permits has been made applicable to any diggings which may be proclaimed in future.¹ These measures, together with the exhaustion of the Lichtenburg fields, reduced the output of alluvial stones to 918,706 carats at £3 6s. 9d. per carat in 1930.

The London Diamond Buying Syndicate had been formed in 1893 to market all the diamonds of the chief South African producers, and after the War it made further agreements with the South-West African interests, formerly the Union's largest competitor. But other countries began to assume prominence in the industry and South Africa gradually lost her dominant position. Whereas she produced 76 per cent. of the world output in 1913, in 1925 the percentage had dropped to 57. By this time the Syndicate had ceased to be a reliable check, and the Diamond Control Act was passed in 1925 enabling the Union Government to control the mining and disposal of stones in the absence of an approved producers' agreement. The mines set up a more powerful syndicate, and its operation and the abnormal demand that existed during the 'boom' period in the United States (which took 80 per cent. of the world production) helped to protect the market from the shocks caused by the phenomenal increase in supplies from the Transvaal and Namaqualand alluvial fields referred to above. But the economic crisis of 1929 again placed the industry in a precarious position, and eventually De Beers, which had bought controlling interests in the other important companies of South Africa, floated a new organization, the Diamond Corporation, Limited, which replaced the old Syndicate and took over the accumulated stocks. This centralization opened the way for an agreement between the government and De Beers. Each member of the association, including the government, which as is shown above had now a direct interest as producer, received a fixed percentage of the trade, and the sale of diamonds was entrusted

¹ *Ibid.*, p. 150.

to the Diamond Trading Company, Limited, a subsidiary of the Corporation. An Act of the Union Parliament established Kimberley as the only place of export for diamonds in the Union; sales of uncut stones were allowed at three centres only—Kimberley, London, and Amsterdam—at uniform prices. Further, the Corporation, under agreement with the companies working important deposits in Belgian Congo, Angola, and British West Africa, buys all their stones and markets them with the South African diamonds through the same channels.

From the first discoveries of diamonds in 1870 up to the end of 1934 the value of the Union's output exceeded £316,000,000, and the net dividends of the producing companies have amounted to more than £80,000,000, excluding the profits of individuals prior to the company era and subsequently on the alluvial diggings. This wealth has probably been greater than that which has been obtained from any other commodity in the same time anywhere in the world, when the size of the industry is taken into account.¹ During the depression period sales fell to a sixth of their maximum and the South African mines ceased to work; in 1934 the production fell to 440,313 carats. Early in 1935, signs of recovery appeared and some of the mines resumed operations. Meanwhile, deposits that have been discovered or are suspected to exist in Namaqualand and elsewhere remain untouched. South African diamonds are used chiefly for gem purposes, and in value the sales exceed the total production of all other countries. In quantity, however, the stones from other parts now form approximately two-thirds of the world output. Various African territories have been responsible for reversing the balance, as will be seen from the following table:

TABLE XVI
Diamond Production in Metric Carats
(In thousands)

	1913	1920	1927	1932	1934	1935	1936
South Africa . . .	5,300	2,612	4,708	798	440	677	624
South-West Africa . .	1,570	606	683	18	4	128	185
Belgian Congo	231	281	3,872	1,450	3,168	4,600
Gold Coast	0.1	461	842	2,392	1,350	1,415
Sierra Leone	0.75	68	295	616
Angola	93	201	367	453

¹ S. H. Frankel, *op. cit.*, chap. iii, pp. 52 ff.

(b) *South-West Africa*

In South-West Africa pipes of kimberlite were found shortly after the German annexation, but in spite of systematic prospecting no diamond has been found in the concentrate. The country produces detrital stones, which, though small, are of exceptional brilliance. The chief alluvial deposits occur in patches over a stretch of 300 miles from the mouth of the Orange river to Conception Bay. Before the War, one South African and fifteen German companies extracted diamonds from the gravel; after the War the Consolidated Diamond Mines of South-West Africa bought the German interests, and now control 80-90 per cent. of the annual sales. The discovery of the Namaqualand deposits¹ led to active prospecting on the north bank of the Orange river, and diamond-bearing terraces were found that are likely to become important when the market recovers. In 1927 the government prohibited prospecting on all surveyed farms along the Orange and unsurveyed government ground up to two miles from the river. The whole of the Kaokoveld was afterwards closed to prospecting for diamonds. Work ceased on the Consolidated Diamond Mines diggings in 1932, but was resumed in 1934. The maximum number of diamonds won was 723,877 carats in 1927; this sank as low as 2,374 in 1933; it was 196,803 in 1937. The price has varied from a maximum of 126s. a carat to 34s.

(c) *Tanganyika, Gold Coast, and Sierra Leone*

At least forty kimberlite occurrences have been found in Tanganyika in the Districts of Mabuki and Shinyanga and on the Iramba plateau, but so far production has been confined to superficial deposits near the pipes, chiefly from the Sultan Mine near Shinyanga. Claims were pegged as far back as 1910, but operations began on a significant scale only in 1925. The value of the output reached a peak in 1927 with £101,480 and declined to £1,859 in 1932, the figure for 1936 being £6,252. In the Gold Coast the first discovery of diamonds was made in 1919 by the Geological Survey near the Birim river. The stones have since been found over a wide area of some 10,000 square miles. They

¹ See above, p. 1513.

are small, and are used mainly in industry and the 'small jewelry' trade. They occur in payable quantities in the Birim river basin, where deposits are being worked near Akwatia and Atiankama by two large companies, the African Selection Trust and the West Diamond Syndicate, and by some smaller concerns, and in the Bonga valley, south-west of Tarkwa, where they are being worked by the Africans. In 1936 1,489,410 carats, valued at £601,636, were exported. In Sierra Leone, after officers of the Geological Survey had found diamonds on the banks of the Gbora river during 1930, an exclusive prospecting licence over the whole territory was granted to the Consolidated African Selection Trust, which has carried out prospecting with encouraging results. In 1936 the output was 616,200 carats, valued at £725,000, which considerably exceeds that for 1935, which was 295,483 carats, valued at £402,000. The same company also holds the sole right of prospecting for diamonds in Nigeria, where stones were recently found in gold workings, but production has not yet begun.

(d) *French Africa, Belgian Congo, and Angola*

The first discovery of diamonds in French Equatorial Africa was made in 1914-15 in the neighbourhood of the Ippy. A company was organized to prospect for two years in the region of the Ubangi-Shari, but it met with no success. Prospectors sent out in 1926 by the *Compagnie Équatoriale de Mines* located diamond deposits 120 kilometres north-east of Ippy, in the region of Bria; further searches revealed workable alluvial deposits north of Bria, and exploitation began in 1931 with an output of 1,509 carats.¹

The Belgian Congo has supplanted South Africa as the country producing the largest weight of diamonds. Kimberlite deposits, some of them diamantiferous, have been found on the Kundelungu plateau in Katanga, but none has proved worthy of exploitation. The Congo stones come from alluvial ground located in several parts of the Katanga Province, by far the most important being deposits that extend from the basin of the Kasai river over into Angola, the whole area of 150,000 square miles constituting the

¹ J. L. Middleton, 'Diamonds in Equatorial Africa', *Engineering and Mining Journal*, vol. 138, 1932. Imperial Institute Publications, *Gemstones*, 1933.

largest alluvial diamond field in the world. The first discovery was made in 1911, but exploitation could not begin until a motor road had been constructed to the navigable head of the Kasai river in 1913. The centre of operations is Tshikapa, and five large companies are now at work, all of them off-shoots of the Belgian-American organization, the *Société Internationale Forestière et Minière du Congo*, generally known as the *Forminière*. The government holds half the capital of the *Forminière* and of the subsidiary concerns except one, the *Société Minière de Bécéka*, which pays half-profits to the state after deducting an agreed amount for the reserve fund and 5 per cent. for dividends. Exports from the Congo were 4,634,266 carats in 1936, an increase of 22 per cent. over the previous year.

The Angola fields, a continuation of the Belgian Congo deposits, are worked in the Lunda District close to the border by the *Companhia de Diamantes de Angola* (*Diamang*), which holds mining rights in the territory tenable up to 1951. The *Diamang* is an off-shoot of the *Forminière*, and began operations in 1913. As in the Congo, production has greatly expanded in recent years, and exports grew from 239,000 carats in 1928 to 444,496 carats in 1934. The marketing of stones is handled exclusively by the Diamond Corporation.

IV. ADMINISTRATIONS AND THE MINERAL INDUSTRY

(a) *State Mining*

It will have been seen that in only a few instances have mineral resources been directly exploited by government agency, and then only for exceptional reasons. The Alexander Bay diamond diggings were taken over by the South African Government at a time when over-production threatened the diamond trade,¹ and the institution of state ownership obviated the choice between opening the fields to general prospecting and reserving them for the large combines. The Transvaal administration worked a tin mine in Potgietersrust during 1907 and 1908, mainly in order to relieve unemployment, but the undertaking proved unprofitable and was sold. The provision in the Transvaal Precious and Base Metals

¹ See above, p. 1510.

Act of 1908, which empowers the state to undertake mining, has not been operated. The Enugu Colliery in Nigeria was developed during the War, and the bulk of its output is consumed by government services.¹ The development of the Kilo-Moto gold mines in the Congo by state agency ended in 1926,² though the state has retained a large share in the joint stock company now operating them. It is a characteristic of the Belgian system that the state retains a share in all the companies developing minerals and diamonds, preferring this to a system of royalties or taxation of profits; the system has some similarity to that in force in the Union in regard to the leasing of gold mines.³

(b) Geological and Mineral Surveys

The administrations have, however, made their own contribution to development in an indirect form by the institution of geological and mineral surveys. In South Africa the Geological Commission for the Cape was organized in 1895, followed by similar organizations in the Transvaal and Natal, and in 1912 these were united to form the Geological Survey of South Africa. In several of the other territories mineral surveys were arranged with the aid of the Imperial Institute, and these led up to the establishment of geological surveys, which came into being towards and after the end of the War, partly as a result of the recognition of the value of minerals for military as well as economic purposes. Survey Departments exist now in all the British territories except the Gambia, where a special investigation was made by an officer from the Gold Coast, and Northern Rhodesia, where all geological work has been undertaken by the mining combines.⁴ The Departments have made important discoveries of valuable minerals, particularly in the West African territories, but their primary object is to provide geological data by systematic mapping of the country, and thereby to indicate where rich mineralized areas are likely to be situated; the work of locating workable deposits is, with good reason, left to commercial enterprise. Some territories, such as Nigeria, have concentrated on the study of

¹ See above, p. 1502.

³ See below, p. 1523.

² See above, pp. 1507-8.

⁴ See above, pp. 1495-6.

water supply and there has been a shortage of technical staff for other investigations.

It must be noted, moreover, that governments have differed widely in the view which they have held concerning the importance of geological surveys and the provision necessary for them. In some territories such survey is of the character of a mere reconnaissance and has rendered only minor assistance to development. This is the case particularly in Kenya, where there was no official geologist previous to the discovery of gold at Kakamega.¹ The provision of an adequate staff for such work presents difficulties; without specialist workers in subjects such as petrology and palaeontology, geological survey cannot be carried out effectively; geological facts must, moreover, be studied over wide areas, so that limitation by state boundaries tends to retard progress. For these reasons the amalgamation of existing geological surveys in groups has frequently been advocated.² Each of the major French territories has a permanent Geological and Mining Department. In the Belgian Congo much of the geological survey has been left to the companies holding mining concessions, and the *Union Minière* in particular has surveyed the southern region of the Katanga in close detail. In addition, numerous temporary commissions have been sent out from Belgium, and a comprehensive programme of mapping is undertaken by a commission in Brussels.³

The direct influence of governments on mineral development, however, is seen more prominently in the conditions laid down for prospecting and winning metals and the claims made on the product whether by way of royalty or taxation. Regulations of this type can have a profound effect on prospection and mining, the more so as they also determine whether development shall be in the hands of the small prospector or capitalist, or entrusted to large financial organizations. The character of these regulations in turn is shaped to a great extent by the system of tenure applied to mining rights. A study of the existing regulations dealing with prospecting or the grant of licences to win minerals reveals a great

¹ Chap. XII, p. 751.

² E. B. Worthington, *Science in Africa*, 1938, chap. iii.

³ See the *Atlas du Katanga* compiled by H. Droogmans, M. Robert, and G. Maury, published by the *Comité Spécial du Katanga*, 1928 onwards.

diversity of local practice which it would be of little value to examine in detail. Taking, indeed, areas in which there is a similarity of general policy, such as the British and French colonies, the diversity of detail in the rules applicable is difficult to justify on any ground of principle and cannot fail to be embarrassing to prospecting interests; there seems, for instance, no benefit in maintaining in neighbouring territories differences in the detail of prospecting fees payable, the area over which an exclusive licence operates, or the time for which it lasts. For the present purpose it is advisable to confine the study to four principal topics: the position taken up by different states in regard to the ownership of mineral rights, the regulations regarding prospection over land in the occupation of natives, the value which is attributed to development through the individual prospector or small capitalist, as against the larger financial organization, and the policy followed in taking a share of the proceeds of the mineral industry for public revenues by way of royalties or through taxation.

(c) *The Ownership of Mineral Rights*

In South Africa, in accordance with the principles of Roman-Dutch law, ownership of land included all values in the land, and those who held land in proprietary title were held to own the mineral rights. But the discovery of the Kimberley deposits and the subsequent activity in prospecting led to a considerable modification of this principle by laws which, though at first applied to the regulation of mining on public lands, were soon extended to private lands, where the state asserted the power to restrict the rights of owners over minerals even when they were not reserved to it by title. In this event the owner could prospect without licence whereas other persons required his consent, except in Natal; the land could not be proclaimed as a public diggings in the Cape and Natal nor in the other provinces without his consent unless he had permitted prospecting, subject to the provision in the Transvaal that the government in certain circumstances could proclaim the land after twelve months' notice to the owner; and he had the entire disposal of mineral rights in the Cape, while in the Transvaal and Orange Free State he was allowed to reserve a portion of his land for mining on his own account, and received a share

of the licence fees paid by claim- and stand-holders.¹ Of late years all alienations of Crown land contain reservations of minerals to the Crown, and the Precious Stones Act of 1927 reserves to the state rights over all precious stones.

In Bechuanaland the Crown recognized the grant of mineral rights included in the original concession to the Tati Company, and it has used the rights which it claimed over all other lands to grant to companies the mineral rights over the majority of the 'reserve' and Crown area lands; part of the royalties will by the terms of these concessions be paid to the tribes in the reserves. In Swaziland the concessions obtained from the King between 1885 and 1889 covered the mineral rights in nearly the whole country, but the Crown has recovered them in twenty-one areas covering approximately 2,000 square miles. In Basutoland no concession of mineral rights has been given. In Southern Rhodesia there was never any doubt from the first that the treaty rights acquired by the British South Africa Company from Lobengula gave it a claim to the minerals,² and the arrangements made on the termination of the Charter left these rights with the Company. They were acquired in 1933 by the Government of Southern Rhodesia for £2,000,000, an investment which at one time appeared to be of doubtful value but which circumstances are now rendering remunerative. Similarly, in Northern Rhodesia the termination of the Charter left the mineral rights with the Company,³ but in this case they were not acquired by the new government, which consequently has no claim to mining royalties.

In Nyasaland the British South Africa Company holds the mineral rights over an area in North and Central Nyasaland amounting to about 9,500,000 acres; over the remaining areas not covered by certificates of claim the Crown has retained mineral rights. In Uganda the owners of the Mailo estates were allowed to retain the mineral rights subject to a payment of 10 per cent. royalty to the Crown, but in all other areas the Crown retains rights over minerals. It has similarly retained such rights in Kenya⁴

¹ Acts 31 of 1898 and 16 of 1907 (Cape); Act 43 of 1899 (Natal); Ordinances 3 of 1904 and 8 of 1904 (Orange Free State); Act 35 of 1908 (Transvaal).

² See Chap. XII, p. 732.

³ Ibid., p. 739.

⁴ In the coastal areas of Kenya the rights of the Crown are doubtful, and where titles have been issued the right of minerals goes with them.

and Nigeria, although in the latter territory half the royalties received from mining in the greater part of the Protectorate are paid to the Royal Niger Company under an agreement concluded for a period of ninety-nine years. The law in the British Cameroons makes a similar reservation of all mineral rights to the Crown. In the Gold Coast Colony and Ashanti rights to minerals have been held to follow rights in land, and the disposal of them has been left to the native chiefs subject to regulation by the Concessions Ordinance,¹ but in the Northern Territories the Nigerian law has been applied. The northern portion of British Togoland follows the Nigerian law while the southern follows the Gold Coast precedent.

In French colonial areas the state has reserved to itself the right to minerals, which are expressly excluded from any concessions of land made. A Decree of July 6, 1899,² provided for the reservation of the customary rights of natives to exploit minerals, and prohibited the grant of concessions in areas where this right was exercised, but the natives were not treated as the owners of the sub-soil rights. It is in pursuance of these provisions that natives work the gold deposits in Siguiri. The reservation of mineral rights to the state has been applied to French Cameroons and French Togoland. The law in the Belgian Congo similarly recognizes the claim of the state to all mineral rights,³ and since the annexation by Belgium any mineral concession has, under the Law of October 18, 1908, required the authorization of the home government. The great mineral concessions given to companies such as the *Comité Spécial du Katanga* and the *Compagnie des Chemins de Fer du Congo Supérieur aux Grands Lacs Africains* in the days of the Free State were maintained by the Belgian Government, which has itself granted mineral rights in a large area to the *Comité National du Kivu*. Ruanda-Urundi has applied the Congo law, which reserves mineral rights to the state.⁴

These differences of treatment have an historical rather than

¹ See Chap. XII, pp. 776-7.

² Decrees of July 5, 1899, Oct. 22, 1926, Oct. 13, 1933 (French West Africa), and July 8, 1926, Dec. 23, 1934 (French Equatorial Africa).

³ Decree of June 8, 1888.

⁴ T. Heyse and H. Leonard, *Régime des cessions et concessions de terres et de mines du Congo belge*, 1932, p. 324.

a logical origin, and it would hardly be of value to canvass now the comparative merits of the system under which the state has retained mineral rights for itself as against that in which they have been allowed to follow the ownership of surface rights. Experience has, however, shown, as for instance in the Gold Coast Colony,¹ that if circumstances or a clearer view of policy had allowed the state everywhere to keep the ultimate ownership of minerals in its own hands, that course would, apart from any gain to public revenues, have allowed of a more beneficial use of these resources for the general native community. The exploitation of mineral rights furnishes a novel type of revenue which native authorities have shown themselves ill fitted to regulate. As was remarked in dealing with surface land rights,² subsequent legislation regulating forms of concession, methods of prospecting, and the like have failed to recover a control which might have been exercised without difficulty and to better purpose under an initial assumption of state ownership.

(d) Prospecting in Native Lands

The Union of South Africa by Act 18 of 1936 prohibits prospecting on land in respect of which the Native Trust or a native is the owner of mineral rights, without the written permission of the Minister, and if the land is proclaimed a public digging the Trust must impose conditions necessary to preserve surface rights to the native occupiers. In Bechuanaland the reserves are closed to prospecting unless the Mining Proclamation has been applied to them, in which case prospecting is allowed under mineral concessions granted by the tribe, with approval from the Secretary of State, or by virtue of a Crown grant issued with the owner's consent. In Basutoland no prospecting is allowed. No special authority is required for prospecting in the reserves of Southern Rhodesia. In Northern Rhodesia, Barotseland is closed to prospecting and the areas occupied by native villages elsewhere are excluded. Unless government specifically closes an area native lands are open to prospectors in Nyasaland, Uganda (except the Mailo lands in Buganda), Tanganyika, and Kenya; in Kenya, however, the consent of the Native Lands Trust Board is required

¹ See Chap. XII, pp. 775-7.

² *Ibid.*, pp. 776-7.

for prospecting in the reserves. In Nigeria, Sierra Leone, and the Northern Territories of the Gold Coast, land under cultivation may not be prospected without the owner's permission; otherwise native lands are open to prospecting, subject to the Governor's right to exclude any area. In the Katanga region of the Belgian Congo special authorization is necessary for prospecting on land in native occupation, and native mining workings in the Belgian Congo and in Ruanda-Urundi are protected.¹ In the French colonies natives retain the sole right to exploit minerals in areas where they have traditionally engaged in mining; these areas were delimited by an *arrêté* of October 1924, and have been extended by the Decree of December 23, 1934, to include deposits which natives have worked continuously for fifteen years.

(e) *Regulations Regarding Prospecting and Mining*

Some indications have already been given, in particular when dealing with conditions in Southern Rhodesia and Kenya, of the different views which have been expressed, sometimes in a controversial form, regarding the respective merits of the small prospector-miner and the large organization, more especially in the exploitation of gold. Here also the choice of policy has seldom been deliberate; it has been dictated partly by historical developments, as for instance in the Gold Coast Colony, under the system by which the native authorities were left with the right of making their own concessions; it has in other cases been determined by the pressure of political requirements, such as the support of a poor white population in the Union or the needs of the farmer-prospectors in Kenya and Southern Rhodesia during the depression period.

South Africa. The history of mining in South Africa affords much evidence of the varied influences which have determined state policy in regard to mineral development. Under the early Transvaal statutes, which curtailed the right to minerals held to attach to the owner of land under Roman-Dutch law, and established the claim of the state to precious minerals,² when ground was proclaimed open for prospecting, the owner and discoverer first received a specified area, and any one member of the general public

¹ Decrees of 1888, 1893, and 1937.

² See above, p. 1518.

could then peg up to fifty claims of 150 by 400 feet. It was soon recognized that this limit retarded development, for the area did not justify the expenditure necessary for efficient working, unless it contained unusually high-grade reef. The amalgamation of blocks into a mineable area involved protracted negotiations, the 'freezing-out' of weak holders, and often the over-capitalization of companies. It was felt that, in order both to avoid the difficulties of the pegging system and to benefit the general revenues, the state itself should act as vendor. The Transvaal Gold Law, Act 35 of 1908, gave the government power to establish state mines, or to lease any proclaimed land, as well as to throw it open for pegging. If it decided to lease, the area was divided into a number of claims, each constituting a workable proposition, and claims were allotted by a Mining Leases Board. Applicants for exclusive mining leases were required to agree to provide adequate capital, and to pay a percentage of profit to the state in addition to licence fees and taxation. The 1918 statute further permitted the Mining Leases Board to lease, without calling for tenders, undermining rights of small areas which could be exploited profitably only by adjoining companies. By 1936 206 leases had been granted over a total of 79,798 claims, of which 48 were disposed of to 24 companies on a basis of sharing in profits, 132 were sold for cash, the aggregate amount received being £422,445, and 26 were sold for annuities over a term of years, or for payments on a royalty basis, the total revenue from these sources being £43,556,232 up to December 31, 1936. The share of profits received by government is either a fixed proportion ranging as widely as from 1·4 to 10·8 per cent. or, more commonly, it varies with the ratio of profit to gold recovery on a sliding scale so calculated that the company obtains fixed proportions of reductions in costs and of increases in recovery.

The law was again amended in 1934 in order to attract capital for the opening of new deep-level mines. In the past the owner of the mineral rights in a proclaimed private farm was entitled to select an area, called a *mynpacht*, not exceeding in the aggregate more than one-fifth of the proclaimed land, and further adjoining areas could be leased. The amending statute of 1934 extended the *mynpacht* to one-quarter of the mineralized area, with leave to

apply to the Mining Leases Board for the undermining lease of a contiguous area in which, if granted, the government has a share of any profits obtained in addition to taxation; the Act aimed at making it impossible for the owner to select a mynpacht which is not, in the opinion of the Mining Leases Board, a workable mining proposition. The Act guards against the indefinite holding up of mineral areas. The Board may grant a prospecting and mining lease to the owner of mineral rights in private lands who intends to prospect, if it is satisfied that considerable expenditure will be needed to prove the existence of precious metals. Should the owner fail to prospect after notice has been served upon him, the Minister may transfer the lease, in which case the consideration payable for the lease must include a rental that goes to the owner of the mineral rights.

These amendments favour operations by highly capitalized ventures, but South African mining legislation still contemplates developments by small workers. In the Cape the discoverer of minerals may select fifty claims in blocks of a basic size each 150 by 800 feet, but varying in area according as the deposit is of precious metals or base metals. After an area has been proclaimed a public diggings and the discoverer, landowner, and other prospectors have registered their claims, any person may peg up to five claims. The Natal and Transvaal statutes allow prospectors a similar privilege, with local variations as to the size and number of claims, which can be pegged at a rental of 6*d.* per month for a base-metal claim after the first year.

Bechuanaland and Swaziland. While in the Union mineral rights have been directly or indirectly derived from the state, historical developments have in the High Commission Territories led to the recognition of a number of large-scale concessions originally obtained from chiefs. It is of interest to note the extent to which these have been developed. In Bechuanaland mining in modern times has been confined to the Tati District, where the Tati Company derives its rights from a concession obtained from Lobengula in 1887, and confirmed by Proclamation 2 of 1911, but a large area remained unexplored until after 1932, when prospecting was stimulated by the gold premium and special facilities were offered by the Company to the small prospector. In the rest of the protec-

torate the British South Africa, Balkis, and Linchwe Concession Companies hold mineral concessions from chiefs over extensive areas, in which development was suspended pending the discussion of legislation to safeguard native interests, until the promulgation of the Mines and Minerals Proclamation, 1932. This empowered the High Commissioner, with the consent of the owner, to declare any area outside the Tati District open to prospecting, but reserved to the holder of a registered concession the sale of prospecting rights for not more than twenty-five years from the date on which the Proclamation was applied to the concession area. There are said to be difficulties in opening Crown lands to prospecting owing to the preferential but not exclusive right of the British South Africa Company. This Company owns mineral rights in the Tuli and Gaberones blocks, and the Victoria Prospecting Company has lately prospected in the Bakwena and Bamangwata reserves on its behalf.

In Swaziland mineral concessions were granted by the native rulers between 1880 and 1889 over an aggregate area of 6,000 square miles, the Crown retaining the mineral rights in the remaining 684 square miles. The existence of these concessions militated against independent prospecting; it was stated by Sir Alan Pim¹ in 1932 that 'the mining houses who hold the mineral concessions are disinclined to take new risks in distant areas when their capital is required for the expansion of already developed mines'. Proclamation 33 of 1921 imposed an annual tax of 5s. per 100 morgen upon property not adequately exploited. The concession-holders petitioned against the tax, which was never enforced, but a commission² set up in 1924 considered that some provision should be made for the throwing open of concession areas to prospecting. The Mineral Concession Areas Proclamation of 1927 gave concessionaires the choice between carrying on development themselves, paying a tax of 5s. per 100 morgen, or opening their property to prospectors. Of 3,728 square miles covered by 28 concessions, 1,629 were being developed by the holders in 1932, and 2,099 had been thrown open. In the area in which the

¹ *Report of the Commission on the Financial and Economic Situation of Swaziland*, Cmd. 4114, 1932, para. 15.

² *Report of the Swaziland Mineral Development Commission*, *Union of South Africa Government Gazette*, 1201, 1924.

Crown has retained the mineral rights, 564 square miles have been declared open for prospecting.

East Africa. The conditions in the Rhodesias have been referred to on pages 1493 and 1495. The British East African territories make alternative provision for the small prospector, who, if he finds minerals, can claim an exclusive right in a restricted area, and for the large organization by means of the 'exclusive prospecting licence' which gives sole rights over an area extending in Uganda, Tanganyika, and Kenya to eight square miles, which may be increased at the discretion of the administration.

Nigeria. In Nigeria legislation affecting minerals¹ allows for the grant of prospecting rights lasting for a year only, and for licences allowing prospecting in areas not exceeding eight square miles in respect of metalliferous metals and two square miles in the case of precious metals. Mining leases may be granted to the holders of either of these for a term not exceeding twenty-one years and may be renewed for a similar period; the maximum area for a lode lease is fifty acres and for an alluvial lease eight hundred acres. Yearly mining rights to alluvial grounds may be granted in cases which do not justify a lease. There is no limit to the number of rights or leases that may be held by one person or company.

Gold Coast. In the Northern Territories of the Gold Coast mining rights are reserved to the state,² and their disposal is governed by an ordinance closely resembling the British East African statutes; in Ashanti and the Colony, however, they are vested in the native landowners who, in the former, are bound by regulations under which options are prohibited and concessions supervised by the government, whereas in the Colony owners may issue concessions without reference to the administration. The results of this system deserve to be discussed in detail. No limitations as to area and duration were imposed upon concessions obtained before 1895, but the Ordinance of 1900 restricted the area in the case of gold mining to five square miles and debarred any one person from holding concessions over more than twenty square miles. In the succeeding two years over 3,600 concessions were granted, in some cases rights over the same land being given

¹ *Law*, cap. 93; and Minerals (Amendment) Ordinance, 9 of 1927.

² See Chap. XII, p. 779.

to different companies. Many were abandoned when the gold boom collapsed in 1902, but the absence of control has up to the present resulted in much confusion and litigation.¹ Nor were the terms of the concessions favourable to the native communities, whose receipts were limited to a fixed rental at a low figure, however successful the enterprise became. The maximum seldom exceeded £300 to £400 a year; in the eastern part of the Colony the usual payment was £50 consideration money for a five-mile concession of ninety-nine years' duration, and a mining rent of £100 to £250 per annum when production began; while in other parts it was customary to give consideration money of from £50 to £100 and a rental of £200 for 1,000 square fathoms. The profits of some companies increased substantially without benefiting the surface owners, and the right of those owners to a more elastic system has been acknowledged by the Concessions Court. The Court now requires that the lessor shall have the option of a mining lease together with a proportion, usually $2\frac{1}{2}$ per cent., of the net profits in lieu of the rents.

Sierra Leone. The mining laws of Sierra Leone resemble those of the Northern Territories of the Gold Coast; exclusive prospecting licences are granted and mining lease or right titles are issued. In 1934 the Consolidated African Selection Trust obtained from government a monopoly in the exploitation of diamonds in Sierra Leone for a period of ninety-nine years. The Company pays an annual rental of £7,000 and is exempted from other taxation except for the $27\frac{1}{2}$ per cent. of net profits, surface rent, and compensation to landowners payable under the Minerals Ordinance of 1927. It may not without government sanction enter into any agreement for the control of output or restriction of marketing of diamonds produced under licence.

French Territories. As we have seen, the state has retained mineral rights and has made special provision to safeguard native customary mining rights. It is of interest to note, in addition, that in the case of companies the law stipulates that three-fourths of the directorate must be of French nationality. The holder of a *permis d'exploration* may be granted a *permis de recherche* which confers exclusive prospecting rights over an area of five to ten square

¹ See Chap. XII, pp. 776-7.

kilometres and is valid for two years, renewable up to six years, the second renewal being granted only if at least 20,000 francs have been spent on prospecting in the previous four years. The holder of a *permis de recherche* who proves the existence of a deposit within his prospecting area may obtain over the latter a *permis d'exploitation* valid for four years, renewable up to twenty years subject to the carrying out of mining operations. The holder of a *permis de recherche* or *permis d'exploitation* may be granted a concession for seventy-five years with the right to renew for a further twenty-five years at an annual rental of 0.50 francs per hectare for the first six years and 5 francs thereafter.

Belgian Congo and Portuguese Territories. As will have been seen, in the Belgian Congo practically all exploitation has been in the hands of large concessionaire organizations. In Portuguese East Africa the Moçambique and Zambesi Companies each have their own mining laws applicable to the territories administered by them. In the district of Lourenço Marques the Lisbon Government has granted large concessions restricted by law to Portuguese subjects or companies. The most important mining area in the territory is Manica which is worked under concessions from the Moçambique Company. In Angola the *Companhia de Diamantes de Angola*, as has been mentioned,¹ holds exclusive prospecting rights for diamonds for thirty-five years throughout most of the colony and the monopoly of exploitation of all minerals discovered for an indefinite period.

Looking to the facts thus presented it is not easy to draw anything in the nature of a general conclusion as to the respective merits of the alternative agencies in development. Many of the individual prospectors have been men without scientific training who, even if they acquired by experience a rudimentary knowledge of geology, nevertheless depended largely on chance finds. Directing their attention to one or two minerals they frequently missed other valuable deposits. Their efforts were desultory, depending upon economic booms and depressions; and as the nature of the survey carried out by them was rarely recorded for the benefit of others, the same ground has repeatedly been covered

¹ See above, p. 1515.

with a proportionate loss of time and energy. Yet their initiative and persistence have frequently succeeded in revealing the existence of rich deposits and prepared the way for exploitation by a larger concern, itself unwilling to embark on prospecting. The value of the small prospector has been recognized in America, where the State of Nevada instituted in 1933 a system of 'itinerant prospectors' schools' for instructing prospectors in the field and assisting them with equipment. In Africa it is only in Southern Rhodesia and to a minor extent in Tanganyika that the small prospector has received definite assistance from the state.¹

The larger organizations, for their part, have not always had a clear record. If the exploitation of such areas as Katanga, Kilo-Moto, or the Rhodesian copperbelt has been effected by large-scale effort, scientifically planned and systematically pursued, there are other instances, as this study will have shown, where large concessions have for long been left undeveloped. In many cases a search undertaken when money was cheap or metal prices were high has been abandoned when economic conditions became less favourable. The progress of mining in the French colonies, in particular, has been retarded by half-hearted efforts on the part of concessionaires. It has usually been accepted that part of the utility of large-scale concessions lies in the fact that they lead to the collection of information from a large area. But even where their agreements oblige them to disclose such information (as in Kenya and Tanganyika) it is frequently the case that their energies are devoted to the discovery of one or two selected minerals, while other resources are neglected.²

(f) *Revenue and Taxation*

The financial relations between governments and the mineral industry are distinguished by a special feature in that the state, where it has assumed ownership of mineral rights, can, in addition to ordinary taxation, claim a share of the proceeds, representing

¹ See, for example, *Report to the League of Nations on Tanganyika Territory*, 1937, p. 156.

² Sir A. Kitson, *Presidential Address to the Geological Section of the British Association*, 1929. See also S. H. Frankel, *op. cit.*, chap. v, sect. ii.

the public interest in the asset on which the industry is drawing. There are, however, factors which set a limit to the amount at which the state can assess this interest. Mineral exploitation is so important an element in general development that it is impolitic to do anything which would check the flow of new capital into the industry. The speculative element in mining and the heavy outlay required for certain ventures such as deep-reef gold mining¹ or a large copper concern, combined with the fact that the asset often has a terminable life, justifies a return to the investor on a higher scale than that of ordinary commercial profit. Further, the interests of the community demand that the deposits should be thoroughly worked and the maximum amount of low-grade ore extracted, while a heavy demand by the state may lead to the use only of the richer ores. The royalty must therefore be considered only as part of the general tax on the industry.

In examining the methods by which royalty is taken it must be noted that in certain areas it is not available to the state, as for instance in Northern Rhodesia, or the older concessions held in the South African protectorates, or in the Mailo lands of Buganda. In the Belgian Congo the state has usually preferred the method of retaining a share in the profits of the enterprise; the details given of the capitalization of the Kilo-Moto Mines will illustrate the system adopted. It is held that under this system the enterprise is not burdened at the outset with fixed charges, and that state control of labour and welfare conditions can be better exercised through representation on the directorate than by supervision from outside. It is not difficult to conceive of circumstances in which the holding by the state of a large share in an industrial enterprise might prejudice its discharge of its duty to labour or other native interests; but these circumstances could not be held to apply to the Belgian Government of to-day in the same measure as they applied in the days of the Congo Free State.

In areas where royalty is taken some variety of form prevails. One method is to levy a fixed sum per unit of production. Thus, the rate on coal is 3*d.* per ton in Bechuanaland, 6*d.* in Southern Rhodesia, and 30 cents in Uganda and Tanganyika. More frequently the royalty consists of a fixed proportion of the gross value

¹ See above, p. 1488.

of the output. On base minerals the rate is 2 or 3 per cent. in Southern Rhodesia, from 1 to 4 per cent. in South-West Africa, and 5 per cent. in Tanganyika and Uganda. A third form is the sliding scale, adjusted to the value of the mineral. The amount payable on tin in Nigeria, Tanganyika, and Uganda ranges from 2 to 10 per cent. of the value, the maximum being payable when the price is £300 or more per ton. In Northern Rhodesia the royalty taken by the British South Africa Company on copper advances from 2 per cent. of the price when it is less than £55 to 5 per cent. of the price when it is £80 or more, plus 10 per cent. of the portion of the price exceeding £80. On gold the royalty is usually a percentage of value: thus, in the British East African territories and the Gold Coast it is 5 per cent. of the gross sum realized; in Nigeria 6 per cent.; in Sierra Leone 9 per cent. of the market price; in South-West Africa 10 per cent.; and in Southern Rhodesia, in the case of reef or placer deposit claims, $2\frac{1}{2}$ per cent. where the gross value (less refining and similar charges) is not more than £3,000 a month, and 5 per cent. when it exceeds that amount.

(g) *Tax on Profits*

Although a flat rate in one or other form has the advantage of simplicity, it is open to the objection that a light tax enables the richer mines to contribute less to revenue than they can afford, while a heavy tax discourages the opening of small properties or the working of low-grade ore. The Southern Rhodesian Government has attempted to solve the problem by exempting small outputs from royalty, which is not payable on precious and base mineral products which in any one month fall below £200 in value. On iron ore in Sierra Leone 5 per cent. of the assessable profits is payable. The rate on diamonds is 5 per cent. of net profits and an export duty of $6\frac{1}{4}$ per cent. in the Gold Coast, $27\frac{1}{2}$ per cent. of net profits in Sierra Leone, and 60 per cent. of the gross proceeds less 70 per cent. of the approved working costs, together with 10 per cent. export duty, in South-West Africa.¹ Katanga has a unique system by which the royalty is based upon the ratio between profits and capital. The rate increases from

¹ Diamonds Tax Proclamation 29 of 1931.

12 per cent. of profits when the proportion is 7 per cent., to 60 per cent. if the ratio exceeds 35 per cent.¹

The importance of gold mining in South Africa's economic structure has caused the government to devote unusual attention to the question of taxation. All royalties have been replaced by taxes on profits as prescribed in the Income Tax Act, 1925, and the Union has adopted what is perhaps the most satisfactory method of taxation, a formula under which the state receives a share, in some instances exceeding 50 per cent., based upon the ratio of profits to recovery. Any attempt on the part of the mine to vary the ratio to its advantage, as by milling unpayable rock, would inflict losses upon the mine itself. The principle was first applied to state mining leases but was made general for all gold mines in 1933 as a solution to problems created by the abandonment of the gold standard. The Low-Grade Ore Commission of 1930² had reported that 'the mines making small or no profits form so large a proportion of the total gold-mining industry that it has become a matter of vital concern to the country to adopt such measures as will ensure for as long a period as possible the continuance of their operations and bring into commission largely increased quantities of low-grade ore'. The greater cost of low-depth mining, on which seemed to depend the further expansion of the industry at the then existing range of gold prices, pointed to a grave reduction in activities. Calculations of future productivity varied: according to some estimates made in 1927 the crushing capacity would be reduced after five years by 14 per cent., rising after fifteen years to 79 per cent., when the total tonnage of rock for crushing would be 327,000,000.

The Commission considered that a reduction of 2s. per ton in working costs would bring into the class of payable ore sufficient new ground to extend the life of the mines by 50 per cent. Though the operation of the group system has considerably reduced costs, the eventual extension of the payable area was ensured not by a fall in costs but by depreciation in the value of South African currency. Old mines were reopened, and development was pressed forward over a wide area, particularly on the East Rand, but also

¹ Extended by a decree of 1937 to all future concessions in the Belgian Congo and Ruanda-Urundi.

² *Report*, U.G. 16, 1932, para. 26.

in other gold-bearing districts of the Transvaal. Though the average yield of gold per ton milled on the Rand fell from 6.33 dwt. in 1932 to 4.57 in 1935, and the total output dropped by 974,000 fine ounces, its value increased by nearly £24,000,000. The government considered the increase to be of the nature of a windfall, and announced that it would take 50 per cent. of the 'excess profits', but no greater proportion, until March 1938. The Excess Profits Duty Act, 1933, imposed a tax upon the difference between actual profits and a 'standard profit' which would have been earned if gold had remained at 85s. An allowance was made for reductions in the grade of ore milled.

In 1935 the Gold Profits Surtax Act imposed a tax on gold-mining profits over £10,000, which, together with the excess profits duty and income tax, might not exceed 50 per cent. of the excess profits. The working of the system was examined in 1935 by a committee, which found that the tax had strengthened the incentive to mine low-grade ore which had been provided by the rising price of gold, but pointed to the danger that, by increasing the amount of ore milled, in order to reduce taxation, the mines might lower their standards of efficiency. It recommended a basic tax at a flat rate, and a surtax leviable under a formula which would graduate liability according to the ratio of profit to the value of gold recovered. This double form of taxation would, in its view, bring to revenue an adequate proportion of profits earned and also stimulate the mining of marginal ore. As a result of these proposals, and in recognition of the fact that the 'standard price' of gold has now only an historical significance, the principle of taxing excess profits has been abandoned. Act 34 of 1936 reduced the normal tax on profits to 3s. in the pound and introduced a graduated rate with a maximum of 35 per cent. determined by a formula which depends upon the percentage ratio of profits to gold recovered, and becomes effective when the ratio is $12\frac{1}{2}$ per cent. and upwards, but with a diminishing abatement of £20,000. Whilst the tax will not reduce the burden on the industry as a whole, its incidence is considered to be more equitable and has the additional advantage of being easily calculable. The framing of a tax policy to encourage the mining of low-grade ore has been inspired by a desire to keep the mines working as long as possible.

V. LINES OF FUTURE DEVELOPMENT

The facts given in the course of this chapter make it possible to estimate the extent to which the development of the mining industry has influenced the economic history of different territories. Directly or indirectly, it has been of the first importance to the Union, the Rhodesias, and the Congo. Though important in the Gold Coast, it has there shared its position with native products, such as cocoa or palm oil; it is only of recent years that mining has formed an element in the economy of Kenya, Tanganyika, or Nigeria; it is still a feature of relatively minor importance in Nyasaland, Uganda, French West and French Equatorial Africa, or the French and British mandated territories in West Africa. In the past the main factors which have influenced the development of mining have been the relative abundance and availability of the metals for recovery, the cost of transportation to the consuming centres, and the cost of labour. The development of the railway system has largely followed the lines of mineral exploitation,¹ and existing mining areas are, on the whole, adequately served, but the great distance of haulage from the interior to the shipping ports will, in a large number of cases, continue in some measure to affect the prospects of expansion. Much of mining development is based upon the assumption that native wage rates will be stabilized at the existing low level, and here, though the wage factor will no doubt be materially affected by the increase in the standard of living or productivity of the native cultivation, Africa will no doubt be able for some years to count on a relatively cheap supply of labour. The expansion in the growth of commercial crops is likely to be offset by an increasing stimulus to wage earning, following on the improvement in social and material conditions in Africa, and on the increase in the numbers of the population.

The minerals have for the most part been exploited in an order that conforms to a scale of values which has prevailed in world markets for several hundred years, namely, first precious metals and stones, and then successively tin, copper, lead, zinc, and iron. In most territories the industry is still largely in the first

¹ See Chap. XXIII, p. 1565.

stage. Reference has been made to the reasons for the relative neglect of base minerals. It can hardly be doubted, however, that the further industrialization of Africa will provide both incentive and opportunity for the mining of the cheaper minerals. The Union of South Africa may be regarded as being on the threshold of this stage. We may expect also more precise geographical definitions of potentially mineralized fields and, as the possibilities of making new finds decrease, a greater intensity in exploring the known mineral regions. Until investigation has reached a more complete stage it would be premature to form an opinion of the extent of Africa's mineral resources. In South Africa, which has been the subject of closer study than other parts of the continent, the government Mining Engineer has recently estimated that the gold, diamond, and platinum wealth below the surface which can be economically extracted is at least twice the amount produced in the last sixty years, and that the value of base minerals should be assessed at not less than £33,000,000,000, or ten times the value of the precious metals. He pointed out that this wealth will be released only under favourable market conditions over a period of many decades, possibly of many centuries. Experience may, on the other hand, eventually show that the Union is no richer in minerals than some of the other territories; there are large areas, notably in the French colonies, which have received little systematic attention from geological surveys.

In most territories the metal industry may be regarded as being in its initial stages from another aspect. Experience in countries with a long history of mineral production has shown that in its infancy crude ore is usually exported, but, as the number of mining operations increases, smelting and refining plants are established internally to treat domestic ore, and eventually ore imported from less industrialized regions. In South Africa the Rand Refinery, Limited, created in 1920 as a private company by the companies belonging to the Chamber of Mines, refines the gold bullion of the Union and also of Rhodesia. Smelting works were erected in Natal in 1912 to work up iron and steel scrap from the mines, but the production of pig iron from South African ore began only in 1926. To develop the industry the government found it necessary to constitute, under state control, the South Africa Iron and Steel

Industrial Corporation, Limited,¹ with a capital of £6,000,000, the major portion of which has been subscribed by the state and the Public Debt Commissioners. The plant commenced operations in 1934 and produces annually about 200,000 tons of ingots, from which approximately 180,000 tons of finished steel products are obtained.

Apart from the Union the only territories with refining and smelting works are Northern Rhodesia and the Belgian Congo. Here the copper ores are crushed, concentrated, and smelted in plants that were erected when production commenced. The bulk of the metal is exported in the form of blister copper, but each territory has an electrolytic refinery. Zinc is refined in Northern Rhodesia, while vanadium is shipped as a concentrate. The reef gold produced in the Belgian Congo is refined in a flotation plant on the Nizi river, tin is smelted in the Katanga, and uranium is exported to Oolen in Belgium, where radium is extracted. A plant for the treatment of refractory gold concentrates is under construction by the Southern Rhodesian Government at Que Que. It is possible that an expansion of the mining industry in other regions will effect a similar process of industrialization, which may diminish the predominance of agriculture that now characterizes the economy of most territories. The immediate need would appear to be a thorough study of resources, which will necessitate a more systematic policy in regard to geological survey than many governments have hitherto adopted.

¹ See above, p. 1491.

CHAPTER XXIII

TRANSPORT AND COMMUNICATIONS

I. INTRODUCTION

THE economic and engineering problems of transport in tropical Africa have necessarily differed from those of countries with a long history of industrial development. In Europe the evolution of the transport system formed part of the transition to an industrialized economy; the process was therefore that of supplementing or displacing one form of transport by another, under the influence of new inventions and an expanding trade, and it served to connect existing towns and manufacturing centres with seaports by lines passing through well-populated areas. In other and less developed countries the growth of transport facilities has generally been aided by conditions more favourable than those which are found in many parts of Africa. The railways in India could rely upon a large passenger traffic, which from the first three years onwards has always yielded a greater return than the receipts from goods traffic;¹ in the United States an extensive network of waterways and roads had opened up large fertile areas for settlement, and a considerable local industry had been created before the beginnings of railway transport;² while in Canada and Australia the building of trans-continental lines was undertaken in the expectation of attracting to rich agricultural areas large numbers of European settlers whose activities would rapidly provide an adequate volume of remunerative traffic. In Africa it has not been possible to base the transport system upon a large internal crosswise traffic, and the first stage of development has been to provide means of conveying raw produce from the interior to the coast for export, and bringing manufactured imports back to the inland dweller. Not only, however, is the building of a main line running inland from the coast expensive in relation to earnings, because of the long distance to be covered and the sparseness of the population, but the further

¹ Horace Bell, *Railway Policy in India*, 1894, p. 4.

² W. M. W. Splawn, *Government Ownership and Operation of Railroads*, 1928, pp. 336-69.

development of connexion through branch lines and roads with surrounding districts is made uneconomic because African crops are frequently of small value, and available only in small quantities.

But transport has had a place which is not less significant in the human than in the commercial history of Africa. When the British Parliament voted in 1892 in favour of undertaking the survey of the Uganda Railway, it was primarily on the ground that the slave trade, hitherto attacked only on the coast, must be dealt with also in the interior.¹ The African Lakes Company, which introduced steamer transport on the East African lakes, was organized in order to help in the campaign against Arab slave dealers. But it is in their effect on the use of head portage that modern systems of transport have made the most impressive changes. In most parts of Southern Africa portage was rendered unnecessary by the use of ox wagons in cross-country transport, though in certain areas, as for instance between Lourenço Marques and Lydenburg in the 'seventies, the presence of tsetse fly led to the employment of native carriers. In the Kalahari and the Sudan the camel is the principal means of transport, and in Northern Nigeria and the Northern Territories of the Gold Coast camels, donkeys, ponies, and oxen have all been taken into use. But in most regions of tropical Africa, and more especially where the tsetse makes the maintenance of domestic animals impossible,² the native porter was the only means of transport. During the earlier days of European occupation large demands were made on the population for the supply of porters, with the inevitable result of much suffering and a large loss of life;³ and it is further clear that the extensive use of human portage was responsible for the spread of forms of disease which had hitherto been local in their incidence.⁴ No estimate can be formed of the demands thus made on the population. But, to take one example, we know that during the War the purchase of 4,200 tons of foodstuffs by the French Government involved the employment of 125,000 carriers.⁵ As late as 1924 the

¹ Cmd. 6560, 1892, p. i.

² See Chap. XIII, p. 929.

³ The death-rate among carriers during the War period was, of course, abnormal, but the average loss from death and desertion of carriers with the Congo troops between 1917 and 1918 is stated to have been 242 per thousand.

⁴ See Chap. XVII, pp. 1129 and 1200.

⁵ L. C. A. and C. M. Knowles, *The Economic Development of the British Overseas Empire*, 1924, vol. i, p. 144.

transport of government loads in Tanganyika accounted for 400,000 working days of the porters employed.¹ At every stage in the expansion of mechanical transport the use of head portage has declined, and it is not without reason that a Belgian writer has spoken of modern means of transport as 'un bienfait immense pour les populations désormais délivrées du fléau du portage'.² The possible scope for the future extension of railway facilities will be discussed at a later stage; but it may be said here that, from the point of view of the African native, the most pressing need at the moment appears to be the provision of forms of conveyance which will, in substitution for head portage, convey produce to the nearest market or railway at an economic rate. But it will be convenient at this stage to make a closer survey of the various transport systems now in operation.

II. HEAD PORTERAGE

The extent to which governments now use head portage for official or other purposes has been discussed in a previous chapter; it will be seen that policy has been consistently directed to reducing the element of compulsion in obtaining it.³ Recorded statistics of portage do not, however, include more than a small proportion of the total number actually engaged in head transport; if the use of the system by the administration has diminished, it is probable that the growth of commerce has in some parts led to an increase in the extent to which natives carry loads on their own account, and it is certain that in the tropical regions many thousands of tons of produce are still being transported by this means, often for great distances.⁴ It has been calculated that as many as 2,000 men are required to transport 100 tons of produce a month over a distance of 100 miles. A variety of calculations has been made in order to arrive at a formula which would enable comparison to be made of the cost of portage with that of other forms of transport. That mentioned by the Rt. Hon. W. Ormsby Gore in the report on his journey in West Africa in 1926 is interesting, though it

⁴ See The Rt. Hon. W. G. A. Ormsby-Gore, 'Some African Problems', *Journal of the Royal Society of Arts*, vol. lxxiii, 1925, p. 803.

would not hold good in present conditions; he compared head portorage at 2s. 6d. with motor transport at 1s. 0d., camel transport at 9d. and 10d., and railway transport at 2d. a ton mile.¹ There are, of course, wide variations in cost, and cost moreover increases as the quantities carried increase, becoming prohibitive before they reach proportions substantially larger than the amount produced at present by native agriculture. Even head portorage undertaken by a native bringing his own produce to a collecting centre is limited in regard both to quantity and distance, for the human carrier, like the pack animal, must carry his foodstuffs in addition to his load. Moreover, apart from the question of cost, there is the grave objection that head portorage is more wasteful of labour than any other form of transport.

III. WATER TRANSPORT

(a) *Waterways of South, Central, and East Africa*

If head transport is the most costly, water is normally the cheapest means of transport. West Africa is more favoured in the matter of waterways than South and East Africa; but, generally speaking, Africa is unfortunate in the fact that no other continent has rivers so poor for navigation in proportion to their size.² The Union has no navigable river; the Limpopo is only navigable for about thirty miles from the mouth; the Zambesi has three navigable sections, but they are divided by impassable barriers; the rivers in Kenya and Tanganyika are impassable or can only be used by shallow-draught vessels. With the exception of the Nile and the Congo river systems, internal water transportation of any magnitude is confined to the great navigable lakes, Nyasa, Tanganyika, Victoria, Kivu, and Albert. The navigable rivers and the great lakes were fully used before the construction of railways. The opening of the line from Beira to Chindio in 1922 diverted much of the traffic which had passed along the Zambesi through Chinde, but produce from the estates on the river banks, estimated at about £250,000 yearly, and a part of the hinterland traffic from Tete is still sent down the river.³

² Sir Charles Lucas, *The Partition and Colonization of Africa*, 1922, p. 14.

³ *The South and East African Year Book*, 1937, p. 905.

The connexion now effected by means of the Zambesi Bridge with the Nyasaland railway system provides through rail communication from Beira up to Chipoka on Lake Nyasa,¹ and the proposed improvements of the steamer services of the lake may in effect extend the traffic highway for a further 300 miles into the heart of Central Africa. The first steam vessel on Lake Nyasa, or any African lake, was launched in 1875, being carried from the coast in 50-lb. loads by 800 porters; there is now a steamer which maintains a monthly round service and also a motor-driven boat. The improvement in communications has opened up southern Nyasaland, the considerable British and Portuguese areas surrounding the lake, the Lilongwe District of Nyasaland, and the Fort Jameson District of north-eastern Rhodesia, and has established conditions under which crops other than tobacco can be grown for export.²

Lake Tanganyika, which measures 450 miles in length, serves a considerable tract of country, but the volume of traffic is relatively small. The Tanganyika administration operates a small passenger launch and a steamer on a fortnightly service from Kigoma to Albertville, the main lake port for the Belgian Congo;³ the lake is also connected by motor road with Abercorn in Northern Rhodesia. The Belgian Great Lakes Company also runs a weekly service between Albertville and Kigoma, and maintains regular communications with other ports, notably Usambara in Ruanda-Urundi and Uvira in the extreme north. The volume of traffic passing in and out of Kigoma has declined since the opening of the Lobito Bay Railway, which now takes part of the copper from Katanga to the West Coast, a more convenient route than that to Dar-es-Salaam, over which goods have to be transhipped at four points. The anticipated completion of the Belgian railway between Uvira and Costermanville on Lake Kivu will, however, tap rich areas in Ruanda and Urundi and add to the traffic on the lake. In view of this anticipated increase in traffic Brigadier-General Hammond recommended⁴ in 1930 that the steamer service should be augmented and the harbour facilities at

³ For Belgian connexions with Albertville, see below, pp. 1591-2.

⁴ *Report on the Railway System of Tanganyika Territory, 1930*, p. 73.

Kigoma improved. Lake Kivu, which is 62 miles long, has a passenger steamer operating in conjunction with the vessels on Lake Tanganyika. Farther west lies Lake Victoria, the largest and, from a commercial point of view, the most important of the great lakes, with a coast line of over 4,000 miles. The first steam launch, brought to the lake in segments by native carriers, was wrecked in launching in 1895; in the following year another vessel was floated, and there are now two steamers of about 1,100 tons and a number of smaller boats, which are operated by the Kenya-Uganda Railway administration; in addition numerous dhows maintain irregular communication between the lake ports. Mwanza Harbour, the terminus of the Tabora-Mwanza branch of the Tanganyika Central Railway, is linked by a weekly service with other points on the lake and has now a large export of cotton. Musoma on the east side serves the adjacent gold-mining districts; Bukoba on the west is the main port for large native coffee plantations; Kabwera to the north is the port of entry for the traffic along the Kagera river, up which a service operates for 97 miles to Nya Kanyasi. The extension of the Uganda Railway from Kisumu to Kampala has had the effect of diminishing traffic on the northern section of the lake; the tonnage carried declined from 140,636 tons in 1929 to 81,125 in 1936.¹ Again, the extension of the railway to Mwanza has caused a certain amount of competition for lake traffic between the Tanganyika and the Kenya-Uganda Railways, to which further reference will be made.² Lakes Kioga and Kwanja in Uganda are not suited for navigation by heavy vessels, being covered with *sudd*; nevertheless, they provide the chief means of communication for a large area, and the administration maintains on them three small steamers and a number of lighters. These lakes provide a link between Atura on the Victoria Nile, which is navigable up to Masindi Port, and Namasagali, which is connected by rail with the main Uganda line, and with Jinja, the northernmost port on Lake Victoria.

The other important waterway in East Africa is Lake Albert, where three steamers and a motor launch operate a total route of 830 miles under the control of the Kenya-Uganda Railway ad-

¹ *The South and East African Year Book*, 1938, p. 800.

² See below, pp. 1579-81.

ministration, which took over from the Protectorate Government in 1924. A service runs between Butiaba on the eastern shore to Kanyonza in the Belgian Congo, which is connected with the gold mines at Kilo-Moto by the Belgian Congo motor transport system; to the north another service operates from Butiaba along the Albert Nile to Nimule, on the Sudan frontier; this route is continued by a motor road to Juba, after which the Nile is navigable to Khartoum. On the south the river Semliki connects Lake Albert to Lake Edward, which in turn is connected by a channel to Lake George; but this line of communication is used chiefly by native fishing-craft and boats carrying salt.¹

(b) *The British West African Waterways*

Of the British West African colonies the Gambia alone has no railway, and relies for transport on its river, which is navigable for about 150 miles by ocean-going steamers, and for a further 140 miles by vessels drawing less than two fathoms. Two small government steamers also maintain a regular service between the numerous ports in the protectorate. The Gambia provides a natural ocean gateway for the neighbouring French territory, but the flow of Senegal trade through Bathurst has declined since the completion of the railway to Kayes.² In Sierra Leone the lower reaches of all the rivers are navigable for light boats, and traffic by these means is considerable. In the Gold Coast shallow-draught launches carry a large traffic on the Volta river between the mouth at Ada and Akuse, a distance of 65 miles; between December and August canoes navigate the river as far as Tamale Port except over the Krachi Rapids, where a mile of tramway has been built for canoe portorage. The lower Volta is an outlet for a small part of the produce from the Eastern Province, which is carried in shallow-draught launches or canoes; palm oil, however, is generally conveyed in barrels, which are made up into rafts and travel down the river to Ada. A private company has a regular mail and passenger service between Ada and Amedica. The next river of importance is the Tano, which is navigated by light-draught launches for 50 miles from the mouth to Tanosu, for about eight

¹ For a description of the craft see S. and E. B. Worthington, *Inland Waters of Africa*, 1933, pp. 153-66.

² See below, p. 1588.

months of the year. The Ankobra is an important highway to the timber districts of Axim and Wiawso and to the gold mines in the former; it is, however, navigable only by light boats, and only for nine months of the year.

~~Nigeria~~ has an extensive network of rivers and connecting creeks, which in parts of the Southern Provinces provide the only means of communication. Commercial interests maintain about 180 self-propelled craft, and much traffic is also carried by native canoes and large rafts. The upper Niger is navigable by shallow draught stern-wheelers as far as Jebba, which is 540 miles from the sea. A private company maintains a weekly mail-launch service between Burutu and Baro, a distance of 407 miles; it also undertakes, together with another company, the transport of passengers and cargo by steamer on the Niger and Benue rivers and in the creeks along the seaboard. The limitation of these services to two companies, and the absence of a carrier in common, have been suggested as reasons for the relatively slow development of the areas in the Southern Provinces, which depend mainly on water transport. The railway line from Kano to Baro was built to make the Niger accessible to regions in the north; the uncertainty of the river services, especially in the dry season, led to the building of the main line from Minna, 111 miles north of Baro, to Lagos, to which the bulk of the traffic now goes.¹ Private motor boats, however, still carry high-rated traffic from the coast to Baro, whence it goes by rail to Kano. During the months when the Niger is unnavigable above Lokoja, where it is joined by the Benue, the shipping companies transfer their craft to the latter river, which is then in flood and navigable up to the French Cameroons. The proposal to close the railway line from Baro to Minna, to which reference is made elsewhere,² would cut off a large part of the country from access to the Niger and curtail the steamer service to Baro, a result which, it is claimed, would prevent the companies from maintaining an adequate flotilla on the Benue. Such an eventuality would be serious for eastern Nigeria, which is dependent for its traffic on the waterway. Farther to the east, the Cross and Calabar rivers are used for transport; ocean steamers go as far as Calabar, 30 miles from the sea, and a mail

¹ See below, p. 1584.

² Ibid.

launch service is maintained between the port and stations on the Cross river, extending a distance of 200 miles to Ikom in the high water season. The Imo and Bonny rivers, with their respective ports of Opobo and Port Harcourt, are the natural outlets for the central Southern Provinces; the Marine Department maintains regular services on the creeks, and commercial firms also run small steam or motor craft in the creeks for trading purposes.

The British Cameroons are served on the western side by the Akwayafe, Meme, and Rio del Rey rivers, which afford a light-draught transport for distances of 30 to 45 miles; on the eastern side the Tiko river is navigable for ocean-going vessels up to the port of Tiko, some 20 miles from the sea.

(c) *The French Waterways*

In French West Africa the Senegal river was the chief means of access to the interior until the railway was built from Thiès, on the Dakar-St. Louis line, to Kayes; this line avoids the great detour made by the Senegal river and also connects with the railway to Bamako and Koulikoro on the Niger.¹ During August and September Kayes can be reached from St. Louis, a distance of about 900 km. by sea-going vessels of moderate size; in the dry months it is accessible only to light-draught stern-wheelers. The *Compagnie des Messageries Africaines* runs a fortnightly steamer service from St. Louis to a point varying according to the height of the waters; in the dry season they cannot pass beyond Podor, above which transport is supplied first by government stern-wheelers and, above Mafou, by barges.² Of the tributaries of the Senegal, the Falémé is the most important; it is navigable for small steamers between July and September for a distance of 170 km. from the junction. Midway between Dakar and Bathurst the Saloum, a tidal estuary, is navigable for 120 km. from the sea to Kaolack. To the south of the Gambia, the Casamance river is open to ships of considerable tonnage as far as Ziguinchor, and to lighter vessels up to 165 km. from the coast. The numerous rivers of French Guinea are made inaccessible to large vessels by rapids, but small craft can ascend some of the streams for a distance of 75 km. The rivers of the Ivory

¹ See below, p. 1588.

² *Le gouvernement général de l'Afrique occidentale française*, 1931, pp. 136-7.

Coast running from north to south form part of the Niger system, and are of little use as waterways; on the other hand, creeks extending along the seaboard from the Gold Coast for about 300 km. are valuable means of communication. In the south-east the creeks, covering an area of 1,000 sq. km., are used by small steamers; a regular service is maintained also for 115 km. from Grand-Bassam to Abidjan on the Ebrié, which is connected by a canal, constructed in 1923, to the Lahou Creek.¹ In Dahomey a large traffic is carried on in the creeks between Porto-Novo and Cotonou.

In the French Sudan water transport has been developed farther than in the other French colonies in West Africa.² The administration maintains a fleet of steamers and lighters on the Niger between Bamako and Kouroussa in French Guinea, and from Koulikoro, the terminus of the railway from Dakar, to Ansongo, a distance of 1,408 km. The tonnage carried between Bamako and Kouroussa declined considerably between 1925 and 1935, consequent upon the abandonment of measures to improve the navigation of the river, a work which according to various commissions of inquiry would entail considerable expenditure, and also on account of the extension of the Kayes-Niger Railway to Thiès.³ The introduction of special tariffs for the carrying of low-priced produce over the railway encouraged traffic to go by rail to Dakar, the shipping facilities of which are superior to those of Conakry, the sea outlet for the Niger region. On the other hand, traffic increased from 4,000,000 metric tons in 1920 to 14,000,000 tons in 1935 on the middle Niger between Koulikoro and Ansongo;⁴ this navigable reach of the Niger forms the logical continuation of the railway from Dakar, which has its terminus at Koulikoro, and it is indispensable in the economy of the Sudan. The stretch of 504 km. of river from Koulikoro to Mopti serves the rich area of which Segou is the centre; at Mopti the Niger is joined by the Bani, navigable for 645 km. to Pankourou, and passing through the productive district of San; above Mopti to Timbuktu, the Niger flows through a series of lakes in an important agricultural region. During the period of the winter rains, from July to January, the

² See *Premier congrès soudanais de technique et colonisation africaine*, 1936, vol. ii, pp. 232-47.

³ *Ibid.*, p. 245.

⁴ *Ibid.*, p. 235.

Niger is navigable for steamers; during the remaining months its navigable stretches are practically closed to all craft drawing more water than a barge. The flow of the river is regulated by a series of natural barrages, in the form of rapids between Bamako and Koulikoro, the lakes below Mopti, and sandbanks at Tosaye, 285 km. below Timbuktu. A noticeable extension during recent years of the low-water period has been attributed to either a widening of the channel at Tosaye or a reduction in the volume below Timbuktu, with a consequent limitation upon the action of the lakes as a regulator.¹ The administration has been working on the problem of restoring the flow to its former proportions by the construction of canals; steps have also been taken to improve the river craft by substituting mechanically propelled vessels for the barges, now used during the low-water season, which absorb a large body of native labour. There are obstacles in the prohibitive price of imported coal or oil, and the scarcity of wood fuel along the Niger; experiments are therefore being made with local fuels, such as vegetable oils.

(d) *The Congo Basin*

In a large part of the hinterland of French Equatorial Africa, together with the north-eastern Belgian Congo, the principal means of surface communication with the sea are the great river systems of the Congo.² Despite its 6,200 miles of navigable waterways, the Congo system has two drawbacks; the course of the Congo river to the sea is broken by the falls at Stanley pool, about 200 miles from the sea, so that access to a port is obtained by the Brazzaville-Pointe Noire Railway on the French side, and the Léopoldville-Matadi Railway on the Belgian. In the second place the middle and upper courses of the Congo and its tributaries are interrupted at critical points by rapids, so that a railway is necessary to carry traffic past the unnavigable passages. But for over 1,077 miles of the middle Congo, traffic by steamers up to 800 tons is possible, and steamers of the same size reach as far as Port Francqui on the Kasai, the principal left-bank affluent of the Congo; Port Francqui is the terminus of the Bas-Congo Katanga railway system which establishes connexion with Élisabethville and

¹ See Chap. XV, p. 1049.

² For a fuller description and map, see W. Fitzgerald, *Africa*, 1934, pp. 291-302.

the Katanga.¹ On the right bank two French companies operate services from Brazzaville to the farthest navigable point on the Ubangi river; the service provides an important administrative link between the sea and the interior of the Ubangi-Shari Provinces. It is of interest to note that the distance from Léopoldville to Stanleyville is nearly the same as that from Juba to Khartoum on the Nile;² but for most of the year the Congo is open to considerably larger craft than that section of the Nile. Free navigation on the Congo, as on other rivers within the conventional Congo basin, was guaranteed by the Berlin Act of 1885;³ in 1929 companies and individuals of different nationalities owned between them 151 steamers of from 15 to 800 tons, and 146 smaller boats.⁴ In the early stages of colonization the organization of river transport was undertaken by the *Marine du Haut Congo*, a department of the administration, which introduced the first steamer in 1881; but in 1919 its services were taken over by a company, formed for the purpose, which in 1925 amalgamated with another organization, and became the *Union Nationale des Transports Fluviaux* (*Unatra*), the only company organized solely for river transport. In 1929-30 the capacity of the Unatra fleet was 50,000 tons, while the volume of cargo carried was 203,172 tons.⁵ The great supply of cheap wood fuel along the upper Congo has made it the rule to use wood-burning steam-engines, although a number of the passenger boats have Diesel engines; it is noteworthy that during the economic depression the Diesel-driven vessels were the first to be laid up.⁶ Various companies besides the *Unatra* maintain fleets, mainly for the transport of their own produce, the most important of these being the *Société des Huileries du Congo Belge*, with a flotilla aggregating 7,400 tons in 1930. On the upper reaches, the *Compagnie des Chemins de fer du Congo* maintains a fleet of 8,300 tons for service from Ponthierville up the Lualaba, one of the headstreams of the Congo, and another of 4,500 tons on Lake Tanganyika.⁷

IV. ROADS

As in the case of railways, the principal obstacle to road construction in Africa is the sparseness of population and its low producing capacity; in addition, the torrential rains of the tropics are a serious complication, suitable material is often lacking, and a shortage of labour in many territories was in the earlier stages of construction made good only by the widespread exercise of compulsion. It may indeed be said that there are territories which owe the greater part of their road system to the use of compulsory labour in the past.¹ But the tracks that were constructed by District Officers in the first stage of occupation, largely with the aid of compulsory or 'communal' labour, became inadequate as commerce and intercourse expanded, and the need to provide more durable roads for motor traffic has involved the formation of technical departments, and a greatly increased scale of expenditure.

(a) Union of South Africa and High Commission Territories

In the Cape, road construction and maintenance was at first in the charge of the Landdrosts and Heemraden, who compiled rolls of Europeans liable for service on the roads; once a year the latter supplied their labour without payment, working under elected overseers, but substitute labour was also accepted. As may well be imagined, the service of the *corvée* was irregularly performed, and the roads ill maintained. There were in addition certain roads which were made by contractors, who as part payment received the right to collect tolls. As the settlers moved inland, they encountered the mountain barriers of the highlands; the farmers performed extraordinary feats in taking their ox-wagons over the Hottentot's Holland Mountains and other ranges, but at the expense of much damage to vehicles and not infrequently loss of life. A turnpike road was made through the Tulbagh Pass in 1807 with convict labour; the French Hoek Pass was constructed in 1824, and the Sir Lowry Pass followed in 1830, being designed to make the eastern districts directly accessible for heavy traffic, which formerly had made a detour to the north via Worcester.

¹ For the use of compulsory labour in road construction, see Chap. XI, pp. 613 ff.

Settlement in the Eastern Province and the growth in commerce made possible by the construction of passes, awakened a strong demand for better roads, and eventually the Central Road Board of 1843 was created, together with divisional road boards. The Central Board was charged to formulate a road policy, to be carried into effect with the aid of state grants, rates, and loans secured by revenue from tolls, and to manage the convict labour which had largely replaced the *corvée*. Between 1845 and 1853 convicts and English workers, introduced at government expense, completed the Montagu Pass, connecting the Little Karroo to George and the coast, Mitchell's Pass from the Bokkeveld to the main Capetown Road, and Bain's Kloof to the interior plateau, on which travelling was easier.¹ The Central Road Board, strongly criticized for over-centralization, was abolished in 1858; it had at the time some 1,650 miles of main road under its charge. The demand that the government should assume direct responsibility for roads was acceded to, but in 1864 policy swung back again, and their maintenance was placed under divisional councils, the intention being to revive the measure of local self-government which had existed under the Boards of Landdrost and Heemraden.

At present the upkeep and construction of roads, excluding those in urban areas, is a function of the provincial administrations; in Cape Province divisional councils receive subsidies from the Provincial Council for road maintenance; in Natal and the Transvaal the maintenance of government roads is purely departmental; in the Transvaal, proclaimed main and district roads are maintained by the Department and some attention is given to an extensive system of farm roads. There is, in consequence, a marked difference between the quality of the roads in different provinces. In 1936 the total mileage of maintained roads was 81,004, and the expenditure on maintenance and construction was £3,009,654, including grants from the National Road Board. This Board was created by the National Road Act of 1935 for the control of national routes throughout the Union, a National Road Fund being instituted at the same time. The Board does not undertake

¹ L. C. A. Knowles, *op. cit.*, vol. iii, pp. 256-7; *The Cambridge History of the British Empire*, vol. viii, 1936, p. 765; *Official Yearbook of the Union of South Africa*, No. 18, 1937, p. 16.

maintenance or construction, which remain provincial functions, but allocates funds for roads which are gazetted as being of national importance, and co-ordinates the work carried out in connexion with them. The funds are mostly derived from the customs tax on petrol and from an initial grant of £500,000 made by parliament. A five-year scheme of works to be undertaken contemplates the maintenance of over 5,000 miles of national roads; the expenditure over the five years is estimated at £11,157,094, of which the petrol tax is estimated to produce £6,000,000, leaving £4,000,000 to be borrowed. A Central Road Transportation Board, with local boards for proclaimed transportation areas, regulates the conditions of the road transport of persons and goods. Road transport has increased considerably in the last few years; in 1933 the total tonnage of goods carried was 554,618, in 1935 it was 1,137,378, and in the same period passengers carried increased from 55,000,000 to about 70,000,000. A large number of road motor-services are now run in conjunction with the state railways.

In South-West Africa two main roads run from within the Union to Luderitz, Walvis Bay, and the Angola border. Little recent road construction appears to have been done. Provision has been made for the election in each magisterial district of a Roads Board with power to levy rates; the government contributes two-thirds of the amount expended on proclaimed roads.

The greater part of Basutoland is mountainous, and pack animals are the usual means of transport. An investigation of the principal bridle paths is being carried out with a view to initiating a programme of construction. The main motor roads traverse the strip of agricultural country running from north to south, and feeder roads or tracks lead from these to the interior. There were in 1936 some 320 miles of gravel and 40 miles of earth main roads. In Bechuanaland a road follows the railway from north to south, about 400 miles, and there is also a road to Kazungula on the Zambesi river, which is an important route for the transport of native labour; the roads are of a low standard and are mostly earth or sand tracks. There are about 1,127 miles of road in Swaziland, only 257 miles of which are first grade. There is no railway in Swaziland, and the territory is served by the motor services of the South African Railways.

(b) Southern Rhodesia

Road councils with elected members have been established in Southern Rhodesia since 1924; they provide a limited degree of local government for rural areas, and closely resemble the divisional road boards of early Cape days. The trunk roads fall under the State Department of Public Works. Until about 1920 most of the roads were little more than veld tracks, passable for ox wagons and carts but not for motor cars, especially in the rainy season, but by 1930 the State Department had provided 6,000 miles of motor roads and the councils another 1,100 miles, while tracks classed as 'other roads' amounted to 2,500 miles.¹ An interesting feature of road construction in Southern Rhodesia is the use of asphalt strips laid on gravelled earth roads in order to provide all-weather tracks along the main roads; the administration aims at the improvement of most of the main roads by this means in the near future; some 1,289 miles had been so treated by 1937. Some further experience seems to be required as to the success of this system, as much appears to depend on the character of the foundation on which the strips are laid. An important factor in the improvement of communications has been the assistance given by the Beit Trust, which up to the end of 1934 had borne the cost of building 91 bridges out of a total of 231; those built by it include the Beit Bridge over the Limpopo, completed in 1929 at a cost of £125,000, and the Birchenough Bridge over the Sabi, at a cost of £128,000. The policy of the government is to take charge of the main road arteries, and to assist the road councils by granting a £ for £ subsidy, in addition to the wheel taxes collected in their areas. A Roads and Traffic Act controlling roads and road transport came into force in October 1936, giving authority to the government to establish road councils for the control of traffic. The improvement in the finances of the territory has given a stimulus to road construction, and a number of extensions are now being made; among the more important is a new road from the Bulawayo-Victoria Falls Road to open up the area of new tin fields.

¹ *Official Year Book of the Colony of Southern Rhodesia*, 1932, p. 448.

(c) Northern Rhodesia

In the absence of branch railways, Northern Rhodesia has had to depend largely on roads for the development of its internal communications. These are of earth, except for two short bitumen-surfaced roads at Lusaka and Livingstone; during the rainy season many roads become impassable and loading is restricted; even in dry weather the surface in many cases is very poor. The arterial system consists of three main routes:—the Great North Road, connecting the settled areas on the railway line with the Tanganyika system and with Lake Tanganyika, a length of 982 miles; the Congo Border Road traversing the copperbelt, and forming a link with the Congo roads, a length of 650 miles; and the Great East Road from Lusaka to Fort Jameson and thence into Nyasaland, a length of 392 miles. There are also some 5,000 miles of so-called secondary roads, but most of these are mere tracks. At present connexion with the Southern Rhodesia system is by an indifferent road from the Victoria Falls via Wankie Colliery to Bulawayo; the construction in the near future of a bridge over the Zambesi north of the Falls, at Chirundu, will afford more direct road connexion between Salisbury and Lusaka. Funds for the bridge are to be provided by the Beit Trustees, who also paid for the construction of the existing Kafue and Luangwa Bridges. The main arterial roads are constructed and maintained by government through the Public Works Department or the agency of the general administrative staff; some 2,014 miles of 'district' roads are controlled by road boards which are financed by grants from government. A sum of £9,349 was spent on reconstructing arterial roads in 1936 and £20,220 on maintenance; the unit rate of reconstruction is £18 a mile, and that of maintenance of the superior type of roads is £7 10s. a mile. Private individuals and companies run motor transport from points on the railway to Abercorn, Solwezi, Fort Jameson, and other outlying stations; but there cannot be said to be any serious competition with the railway, which traverses the centre of the country from north to south and leaves most of the country to be tapped by motor roads. Motor transport is expensive, and is used more for local traffic than for the development of native areas or the carriage of export

goods to the railway, except in East Luangwa Province, where tobacco is carried by road into Nyasaland and also into Southern Rhodesia.

(d) *Nyasaland*

The Nyasaland road system was first developed to meet the needs of European planters and later adapted to provide for the native cultivation of cotton and tobacco as export crops. The natural soil conditions are more favourable to earth-road construction than those of Northern Rhodesia, and only a small part of the system has required surfacing with metal. Some 951 miles of road, of which 96 miles have a macadam surface, are classed as 'all weather roads' and 1,200 as 'seasonal roads'. In addition there are 1,220 miles of tracks usable by light vehicles in the dry season. A main road runs through the northern part of the territory and connects with the Tanganyika system; other connexions are made with the Northern Rhodesia Great East Road, with Southern Rhodesia via Portuguese East Africa, and with the Portuguese roads to Port Amelia and the east coast. The road system serves most of the areas of production in the south of the protectorate¹ and thus acts as a feeder to the railways, but communications are undeveloped in the northern area.² There is in the south a considerable extent of competition with the railways, particularly in the case of the road to Rhodesia which carries tobacco to Salisbury. A Roads Transport Ordinance was passed in 1934, with the object of co-ordinating the transport services and restricting competition.

(e) *Tanganyika Territory*

The Tanganyika roads are based on a war-time system which was constructed with little regard to correct alignment and grading; the available resources for post-War reconstruction have mainly been used in improvements such as bridges and culverts, and in new lines of route to replace unsuitable gradients. In the War much use was made of unpaid or scantily paid labour; the

¹ *Report on the Nyasaland Railway and proposed Zambesi Bridge*, Colonial 27, 1927, p. 18.

² Speech of the Governor at the opening of the Legislative Council, Oct. 1935.

chapter dealing with labour has shown the extent to which any compulsory or unpaid labour is now used on the roads.¹ The recent construction of the road from Mbeya to Chunya in the Lupa gold fields averaged about £300 per mile, and maintenance of main and grade A roads cost some £10 and £7 per mile respectively during 1935; these rates are not unusually high, but the length of the roads makes their maintenance a heavy charge, the sum paid for this purpose in 1935 being £43,746. A considerable programme of constructive work is now being carried out, including a new road to shorten from 464 to 240 miles the communication between the Lupa gold fields and the Central Railway; a sum of £53,412 was spent on construction in 1935. The Public Works Department maintains 2,784 miles of main roads and 1,478 miles of district roads; a further 10,000 miles of roads or tracks are maintained by the district administrations from public funds, and many more miles of tracks are maintained by the native administrations, their cost being met from native treasury funds. Given, however, the large area of the territory, and the character of the existing railway communications, which were designed for strategic rather than commercial purposes, the mileage of main roads is clearly still inadequate. The greater part of both the main and district roads is unsurfaced, and the district roads are for the most part unsuited for traffic in wet weather. The main roads connect Dar-es-Salaam with the Tanga area and Tanga with the Kenya roads via Moa; Nyasa and North Eastern Rhodesia via Dodoma and M'beya, thus forming part of the Rhodesia-Kenya Great North Road; also Iringa and the northern area with Mahenge. Regular motor-transport services for passengers and goods are run by companies and individuals, and growing competition between rail and road services necessitated consideration of means of control or co-ordination of the rail and road systems. In 1936 an inquiry² for this purpose was conducted by Sir Osborne Mance on behalf of the East Africa Transport Policy Board; the Government Committee which examined his report considered that conditions in Tanganyika did not

¹ See Chap. XI, pp. 616 ff.

² Brigadier General Sir H. O. Mance, *Report on the Co-ordination of Transport in Kenya, Uganda, and the Tanganyika Territory*, 1937.

require a comprehensive licensing system to restrict competition, but that a control of goods traffic on routes competing with the railway was necessary in the public interest.¹ The finances of the Tanganyika Railways do not permit of a competitive lowering of rates.

(f) *Kenya*

In Kenya, road making may be said to have begun in 1905 with the construction of feeders to the railway. One of the first roads built was from Fort Hall to Nairobi, formerly connected by a trail of 80 miles, impassable for wheeled traffic owing to bad gradients and dangerous river-crossings. As the expected traffic did not warrant great expenditure, the surface was formed of blocks of *murram* which, when beaten or rolled with water, formed a hard brick-like surface; it became the standard class of road for communication between the more important centres not connected by railway. In Nairobi itself, and generally in the black cotton soil region, the impermeability and great expansion and contraction of the soil made it unsuitable as a foundation for roads, a difficulty which was accentuated by the appearance of motor vehicles. In 1916 it was estimated that the cost of construction of a 16-foot first-class road was £1,091 per mile, as compared with £420 per mile of somewhat inferior road before the War.² In the native areas road making was in the earlier stages carried out by the local population, ordered out by their headmen, under the supervision of Administrative Officers. Construction usually followed existing native paths, with a surface hardened by use, which, however, readily dissolved in the wet season. These roads sufficed for administrative needs, until the motor car gave rise among settlers and tourists to a demand for all-weather roads. It was no longer possible to exact compulsory and unpaid labour on the roads,³ as it was clear that natives would be working on roads having little immediate value to them locally, while others they needed more were neglected; it was found, moreover,

¹ *Report of Committee to inquire into the Question of Competition between Road Transport and Railways in the Tanganyika Territory*, 1937, p. 16.

² A. G. Bush, 'Road Development in British East Africa', *Minutes of Proceedings of the Institution of Civil Engineers*, vol. cci, 1916, pp. 313-17.

³ See Chap. XI, pp. 616 ff.

that the construction of better-class roads required the services of qualified engineers. The Department of Public Works took over responsibility for all main roads, except in remote parts, and the cost of construction rose steeply. The total length of roads in the charge of the Public Works Department is now over 10,000 miles, of which some 3,700 are classed as principal arterial roads. In 1935 some 816 miles had a hard surface, the remainder being earth roads which are not always passable after heavy rains. To protect the railway against road competition, the carriage of goods by motor transport is forbidden, subject to exemptions, along certain scheduled roads running parallel to the railway.¹ Experiments are being carried out with a type of strip construction and a cheap form of bitumen surfacing which it is thought may cost about £300 to £400 per mile. In 1936 a total of £39,990 was spent in European areas on trunk roads and £10,328 on roads in native areas. A committee appointed to investigate the desirability of co-ordinating and regulating all forms of transport presented its report in 1936, and drafted a bill providing for the control of road transport where necessary by licence.

(g) *Uganda*

Uganda is little served by railways, and the growth of cotton cultivation has given special importance to the existence of a good road system. It is fortunate that the protectorate has been able to develop a system of roads that is generally regarded as being among the best in Africa. The main roads are properly formed and graded, and are surfaced with laterite gravel; a factor which has assisted the making of roads of this quality is that the soil (unlike that of parts of Kenya) provides a good foundation, and that supplies of *murrum* are plentiful throughout the country. But Uganda has also profited to an exceptional degree by the well-established customary law, regularly applied in the Buganda Kingdom itself, which has made available a large body of unpaid labour for the roads.² At the end of 1935 there were 2,038 miles of main roads built and maintained by the Public Works Department; of these, 1,189 miles were first-class roads (for wheeled

¹ Carriage of Goods by Motor (Prohibition) Ordinance, 1932.

² See Chap. XI, p. 619.

vehicles up to 9 tons), 526 miles were second-class, and 784 miles were third-class roads. The average cost of maintenance was £19 3s. 7d. a mile. In addition there were approximately 4,800 miles of roads built and maintained by the native administrations.

(h) *Nigeria and British Cameroons*

In West Africa road construction was for some time confined to the coast and the belt of country near the railway lines; from this part the interior was reached by a network of native tracks. Generally speaking, conditions for road construction in West Africa are less favourable than in areas such as Uganda or Nyasaland; thus, in Uganda the construction of a 24-foot wide road with a 9-inch foundation of laterite and a centre width of 10 feet installed with granite has been estimated to cost £200 per mile and £30 per mile per annum to maintain; in the Gold Coast, where road metal is scarce and the climate unfavourable, the cost of constructing a gravelled road for light traffic 16 foot wide has been estimated to cost £800 per mile and £50 per mile for annual maintenance.¹

In Nigeria the road system is now well developed; there are 3,775 miles of road maintained by the Public Works Department, 168 miles with bitumen surface and 3,607 miles of gravel and earth; another 19,338 miles of gravel and earth road are maintained by the native administrations out of native treasury funds. All the roads maintained by the Public Works Department, and 2,192 miles out of those maintained by the native administrations, are open to traffic all the year round. A Communications Board has been appointed to deal with questions of road policy; the general scheme of development approved by it aims at through communication by road from north to south and at further opening up the Logoja and Cameroons Provinces; also at the widening and metalling of existing roads to meet the demands of increasing traffic.² Research on alternative methods of construction is said to have proved that suitable soil grading, with or without bituminous proofing, will provide adequate road surfaces at a lower cost than has hitherto been available. In 1935-6 the Public Works Department spent £89,577 on roads and bridges, exclusive of township roads, an

¹ Sir John Eaglesome, 'Road Constructions in West Africa', *West Africa*, Oct. 16, 1937, p. 1430.

² *Nigeria Handbook*, 1936, p. 101.

average of £24 per mile. The road system acts generally as a feeder to railways; a government system of motor feeder services operates in the Northern Provinces and carried 19,308 tons in 1935-6. But competition with railways by motor transport is increasing, particularly on the Ibadan-Lagos Road which runs parallel to the railway.

In the mandated territory of the Cameroons the Public Works Department maintains 132 miles of all-weather motor roads and the native administrations between 300 and 400 miles of earth roads, but these are in some cases impassable during the rains. Traffic on the Buea and Tiko section of the motor road increased from 100 tons per day in 1935 to between 500 and 600 tons in 1936, and it is proposed to treat the surface with bitumen. The completion of the new Mamfe-Bamenda road has been delayed owing to the difficult country encountered between Mainyu Bridge and Bamenda; this section of 75 miles is estimated to cost £30,000. The Bamenda roads are linked to the French Cameroons' system, providing access to the Duala Railway. The maintenance of roads in the southern area is specially onerous owing to damage by heavy rainfall. Road communications would seem to be less well developed in the northern than in the southern part of the territory.

(i) *Gold Coast and British Togoland*

The 6,200 miles of roads in the Gold Coast are divided into three classes:—those maintained by the Public Works Department, comprising 1,967 miles of gravel roads and 469 miles with a tarred surface; better class lightly gravelled roads, with semi-permanent bridges and culverts; and earth roads with timber bridges maintained by the administrative establishment. The government maintain motor transport services in connexion with the railways, and there are now no large private transport companies operating in the territory.¹ Motor roads extend from Kumasi to Tamale, connecting the railway with the Northern Territories. In 1936 legislation² came into force to prevent the carriage of certain goods over roads which may compete with the railways; as, however, only one through road has been com-

¹ *The Gold Coast Handbook*, 1937, pp. 90-1.

² Ordinance 38 of 1936.

pleted, it is too early to judge whether the restrictions will have the desired effect. The conditions in the Northern Territories would seem to favour the further development of the road system for the transport of produce rather than the extension of railways.

There are no railways in Togoland under British Mandate; communications in the Southern Province section consist of 218 miles of motorable roads, of which 3 miles are maintained by the Public Works Department and 215 by the District Commissioners. In the north the Gold Coast Public Works Department maintains the Tamale-Yendi Road, which is linked to the Gold Coast road system. Yendi is also linked to Accra via Kpandu. The country has a large number of earth roads constructed by the chiefs and maintained from native administration funds; as the revenue of the native treasuries is small and the chiefs are no longer permitted to employ unpaid communal labour, construction of further roads has become difficult.¹ It has been suggested that this problem has an educational value, as bringing home to the chiefs the advantages of direct taxation,² and also the benefit to be gained by leasing land rather than selling it.

(j) *Sierra Leone*

The roads in the Sierra Leone Protectorate are divided into motor roads and chiefs' roads; the latter, which are maintained by tribal authorities, are not usually open to heavy motor vehicles, and are sometimes closed to all motor traffic in the wet season. The motor roads are constructed and maintained by the Public Works Department; mileages are 287 in the Northern Province and 526 in the Southern Province. Some 253 miles of road in Freetown and the peninsula are gravelled with laterite or bitumen surfaced; the other motor roads are surfaced with laterite; there are numerous rivers too wide to bridge, and on these the administration maintains fifteen ferries which are capable of taking lorries. A new motor road, about 80 miles in length, is to be completed in 1939 at a cost of some £400 a mile along the coast of the peninsula, financed from the Colonial Development Fund.³

¹ *Report to the League of Nations on Togoland*, 1936, pp. 12-14.

² See Chap. X, p. 587.

³ *The West African Review*, June 1937, p. 12, and *Colonial Development Advisory Committee, Eighth Annual Report, 1936-7*, Cmd. 5537, 1937.

The maintenance of the provincial motor roads cost £11,155 in 1936. Road competition with the railway route between Freetown and Makeni has caused heavy losses to the railway, but legislation is now in force¹ by which the transport of certain produce or goods from other than local areas is prohibited.

(k) *The Gambia*

In the Gambia the extent of the territory on each side of the river is such that no extensive system of main roads is required, but the district road system, needed for the transport of native produce, is as yet undeveloped. A main road from Bathurst, which branches to Cape St. Mary and to the Kombo North and Central Districts, has 29 miles of its length macadamized.

(l) *The French Colonies and Mandated Territories*

In the French colonies a great amount of work has been done in the last few years in the extension and improvement of the road system. In French West Africa roads hardly existed outside certain urban areas in 1914; in 1937 there were stated to be some 50,000 km. of motorable roads.² The character of the laterite soil found in many parts of French West Africa has allowed roads to be made without special metalling, and though the standards observed would be regarded as unsatisfactory in British areas containing European settlers, the roads are reasonably serviceable. In the more sandy regions of Senegal and in the mountainous areas of French Guinea, construction has been more difficult. The extension of the road system has linked the interior of the country to the railways by a network of roads passable by cars, at least during the dry season. Of the total of 50,000 km. as shown in 1937, the communications classed as main roads had a length of some 13,100 km., the remainder being classed as subsidiary roads and tracks. The road system centres round a main axis formed by the Dakar-Bamako Road which will be linked to the provincial capitals and other parts of the colonies by inter-colonial routes. From Bamako, two main routes are to lead,

¹ Ordinance 6 of 1937.

² *Discours prononcé par le Gouverneur Général de L'Afrique occidentale française à l'ouverture de la session du Conseil de Gouvernement, novembre 1937.*

one to Northern Africa via Gao, an important air centre, and the other to Lake Chad via Niamey. The principal inter-colonial routes are at present from Dakar to Bamako via Kayes (1,290 km.); St. Louis to Kayes (770 km.); Grand Bassam to Bamako (1,191 km.); Bobo-Dioulasso to Niamey (850 km.); Bamako to Kankan (338 km.); Niamey to Savé (770 km.), and a connexion with French Equatorial Africa from Niamey to Zender and Chad (1,430 km.). The inter-colonial routes are the concern of the Governor-General, the local governments financing and carrying out the works approved, according to a general policy. Road construction has been mainly financed by loan funds and maintenance assisted by the system of *prestation*, of which an account has been given in the chapter dealing with labour.¹ Motor transport is increasingly used and in some areas the government runs its own services. In 1924 the growth of road traffic in French West Africa necessitated the promulgation of a Highway Code by *arrêté* of the Governor-General, which was brought into operation for each colony as required by means of local *arrêtés* of the Lieutenant-Governors.² In 1935 the Code was embodied in a decree; its provisions have subsequently been adopted by the Government of French Togo.³ The roads in French Togo have also been developed in recent years as part of the *outillage économique* of the territory; like French West Africa, Togo has drawn largely on loan funds for the purpose. The roads comprise an inter-colonial system of 1,000 km. of all-weather roads linking the principal centres with the neighbouring territories, 600 km. of secondary all-weather roads acting as feeders to the railway, and 1,400 km. of third-class roads or tracks only usable during the dry season.⁴

The system of communication in French Equatorial Africa comprises two inter-colonial routes, namely the Bangui-Cameroon Road from the capital of Ubangi-Shari to the sea and that from Brazzaville to Bangui; a smaller inter-colonial route joins Mitzi-Ojeni and Ebolowa. In 1933 there were in Ubangi-Shari 7,000

¹ See Chap. XI, p. 624.

² Decree of June 21, 1934, amended by Decree of Feb. 14, 1935.

³ Decree of June 16, 1935. See also *Rapport annuel au Conseil de la Société des Nations sur l'administration du Togo pour l'année 1935*, p. 167.

⁴ *Rapport annuel au Conseil de la Société des Nations sur l'administration du Togo pour l'année 1934*, p. 49.

km. of main roads, mostly all-weather routes; Chad had 4,600 km. of roads, but mostly impassable during the rainy season; in the Moyen-Congo, which is served by numerous navigable river routes, there were 3,200 km. of tracks, of which only 500 were considered fit for motor traffic; in Gabon roads are less developed owing to the use of navigable river routes, about 1,000 km. being in use in 1933.

In the matter of communications, as in many other respects, French Equatorial is less advanced than French West Africa. One of the principal obstacles to motor traffic is the existence, particularly in Ubangi-Shari, of large numbers of unbridged rivers or streams, crossed by ferries which are frequently no more than a raft supported on canoes.

In the Cameroons under French Mandate the road system, which had only 430 km. in 1922, had increased by 1937 to 4,000 km. of good-class motor roads and over 1,600 km. of secondary roads passable in the dry season.¹ Here the construction of the road system is for the most part carried out under the supervision of the Administrative Officers, who receive some instruction in road making on their appointment to the African service.²

(m) *The Belgian Congo and Ruanda-Urundi*

In the Belgian Congo the construction of motor roads has in the last few years been systematically developed, in order to provide feeders to the combined rail and river system to which reference has already been made.³ There are now 43,063 km. of motor roads maintained by the state *Service des Travaux Publics*, and encouragement has been given to the formation of motor services, in many of which the state has a financial interest. The *Messageries Automobiles du Congo* (the *Maco*) alone operates 4,800 km. of route. Roads are classified as main arteries and district roads; in 1935 the arterial roads comprised 5,161 km. of principal roads, 7,758 of secondary roads, and 2,206 of less important roads *pour voyageurs*; the district roads, mainly of local interest, were 36,338 km. in extent, and there were also 9,708 km. of private roads.⁴ The amount expended in upkeep of the main roads

¹ H. Labouret, *Le Cameroun*, 1937, p. 149.

² Sir J. Eaglesome, *op. cit.*

³ See above, p. 1547, and below, p. 1591.

⁴ *Rapport annuel sur l'administration du Congo belge*, 1936, pp. 93-4 and 110.

(25,861 km.) was 6,349,341 francs in 1935, or an average of about 246 francs per kilometre, the cost varying between 643 francs per kilometre in the Élisabethville Province for main arteries to 91 francs in the Lusambo District for *voyageur* roads. As in French Equatorial Africa, one of the difficulties of developing the use of motor transport lies in the large number of rivers and streams, the bridging of which would involve a prohibitive expenditure. The extent to which unpaid labourers such as tax-defaulters are used on the roads is referred to in Chapter XI.¹ In the Belgian mandated territory of Ruanda-Urundi roads are classed as in the Belgian Congo; 214 km. of arterial road connect Usumbura-Astrida with the Belgian Congo, and 1,751 km. of second-class roads connect various points in the territories with the arterial road; if *routes pour voyageurs* and private roads are included there were in 1935 some 5,459 km. of roads passable during the whole or part of the year. A considerable extension of the road system appears to be required.

(n) *Portuguese Territories*

In the Portuguese colony of Moçambique a system of earth roads, gravelled in some areas, is gradually being built up. The soil in the coastal areas is sandy and unsuitable for earth roads and maintenance is expensive, but in provinces farther from the coast, good earth roads can be maintained at relatively small expense. The main roads are that from Lourenço Marques to the Transvaal frontier (89 km.), providing access to Johannesburg via Swaziland, and two roads from Tete, to the Southern Rhodesia frontier (146 km.) and to the Nyasaland frontier (128 km.), forming a direct road link between Salisbury and Blantyre, a route used for the transport of Nyasaland produce, and actually competing with the railways. Another road connects with the Nyasaland system from Moçambique (650 km.), and a road from Vila Pery connects with the Southern Rhodesian system at Umtali, 130 km. Some years ago the total mileage of first-class roads was given as 4,822 km., second-class 6,705 km., and third-class 11,003 km. In areas served by motorable roads the regulations forbid native portage. In 1931 some 4,000 km. of earth roads

¹ p. 621.

had been made in the territories administered by the *Companhia de Moçambique*. In Angola there are, in addition to various dry-weather roads, over 15,000 miles of good motor roads: 6,000 miles of these are in the districts served by the railway, and act as feeders to the main line.

V. RAILWAYS¹

(a) *The Union of South Africa*

The history of the construction of railroads in South Africa will serve to illustrate some of the problems of railway finance and management later encountered in other parts of Africa. As has been shown, the transport system could not in South Africa be based on navigable waterways of importance; the factor which actually determined the routes taken by the main lines was the discovery of rich mineral deposits—diamonds at Kimberley, gold on the Witwatersrand, coal at Wankie, lead and zinc at Broken Hill, or copper at Katanga. The first line opened in South Africa was a two-mile stretch of standard gauge, from the Point to Durban, completed in 1860; at that date a line from Capetown to East River, and on to Wellington, was under construction by an English company, holding a guarantee of 6 per cent. on a sum of £520,000. By 1873, when diamonds were found at Kimberley, there were still only 58 miles of railroad in the Cape and 5 in Natal. An extension was urgently called for, in order to carry stores and equipment to Kimberley; but a line from Capetown had to cross mountain ranges, semi-arid country, and plateaux rising to 6,000 feet, while the value of the diamond deposits was still undetermined. The governments concerned, in considering the route which a railway should follow, had in view the possibility of attracting traffic through the Cape ports, with a consequent growth in customs revenue, a consideration that had little significance to private enterprise. In the circumstances, it could not be expected that railway development would be undertaken by companies unless they received substantial concessions,² and, as was shown when proposals were made in 1860–70 to build a line in Natal, there was a desire to avoid commitments that might in

¹ See map facing p. 1537, and fuller map in S. H. Frankel, *Capital Investment in Africa*, 1938.

² On this point see the authorities quoted in S. H. Frankel, *op. cit.*, chap. v, sect. iii.

time prove burdensome to the colonies. But the need for speedy construction was imperative; ox wagons took a month or two months to transport goods from Port Elizabeth or Capetown to Kimberley at £15 to £30 a ton, and coaches or mule carts took seven or nine days for the journey at a charge of £12 a passenger. The Cape Government took construction into its own hands. Acquiring the small private lines to which reference has been made above, it started in 1873 on a standard-gauge railway from the Cape to Kimberley, substituting in 1881 the 3 ft. 6 in. gauge which was subsequently adopted throughout the south. Political pressure from the Eastern Province demanded equality for all the Cape ports, and a beginning was also made on lines from Port Elizabeth and East London. Natal in 1876 began to build coast lines in order to serve its sugar estates and, anxious to share in the trade with the interior, took over the private line at Durban and began to extend it towards the Free State and the Transvaal.

The 650-mile line from Capetown to Kimberley was completed in 1885, when the Port Elizabeth and East London lines were nearing Colesberg and Aliwal North on the Orange Free State border, and the Natal line had been brought as far as Estcourt.¹ This was still the situation when the proclamation of the Witwatersrand as a public gold digging in 1886 and the first gold boom of 1889 presented a new objective for the extension of the South African railways. The line of advance was obvious, but the policies of railway construction could not be separated from considerations regarding the customs duties on goods passing through the ports in transit to the republics. Up to 1889 the coast colonies retained the whole of these duties; in that year the Cape Colony and Free State entered into a customs union, and agreed that the proposed line to Bloemfontein should be continued by the Cape on to the Vaal river, the border of the Transvaal; while Natal, preferring to remain free for a competitive lowering of tariffs, refused to sign the convention, and pushed on its own railway towards the Transvaal. The Transvaal, on its part, was anxious to avoid dependence on the British ports, and had from the first seen in Delagoa Bay the best exit and entrance for its

¹ E. A. Walker, *A History of South Africa*, 1928, pp. 397, 412, L. C. A. and C. M. Knowles, op. cit., vol. iii, p. 259, and *The Cambridge History*, op. cit., pp. 451, 780.

traffic; it organized a system of portage from the Bay, and in 1875 signed a protocol with Portugal providing for co-operation between the two states in the building of a railway to the 'centre of trade' in the Transvaal.¹ But no active steps were taken to promote construction, and the matter remained at a standstill until activity was stimulated in 1882 by the gold rush at Lydenburg. The treaty was then ratified, and preparations were made for a survey of the route by the two governments, each of which granted a concession to a company for building the lines from the respective termini. Money could not, however, be raised for the project, and the Transvaal, under pressure from the miners at Lydenburg, approached Cape Colony in 1885 and 1886 for a customs union and a railway from Kimberley. This the Cape refused, but soon after, when the value of the discovery of gold on the Witwatersrand was confirmed, making it potentially one of the most important markets in Africa, the Cape received in its turn a similar rebuff from the republic. The Portuguese Government now arranged that the construction of the line from Delagoa Bay should be started; the Transvaal attempted to block the extension into its borders both of the Port Elizabeth Railway from Bloemfontein and of Rhodes' continuation of the Cape Railway from Kimberley; in 1889 it at length saw Delagoa Bay linked to the Transvaal border, and forthwith allowed the Netherlands Railway Company to start on the section to Pretoria. Rhodes' line from the Cape, refused a passage through the Transvaal, had to continue its way towards Rhodesia through Bechuanaland; the De Beers' trust deed conferred authority to build railways, and in 1890 the line to Kimberley was being taken from Kimberley to Vryburg, whence the Bechuanaland Railway Company, an offshoot of the British South Africa Company, continued it to Mafeking. The Netherlands Company was now once more in difficulties about raising money; the Transvaal Government was forced to buy its shares and obtain a loan from the Cape, under an agreement which obliged the Netherlands Company to build a bridge across the Vaal and construct within the Transvaal a line which would serve to extend the Port Elizabeth line to Johannesburg and Pretoria. This was completed in 1892, and there

¹ J. van der Poel, *Railway and Customs Policies in South Africa, 1885-1910, 1933*, p. 5.

followed a lowering of rates over the Natal line, in order to compete with the Port Elizabeth railway, which, however, retained almost a monopoly of the Transvaal carrying trade until the Pretoria-Delagoa Bay line was finally opened in 1894.

In 1895, therefore, the position was as follows. The Witwatersrand was linked to the Cape ports, and to Durban and Delagoa Bay, by lines competing as far as the Transvaal borders; inside the republic, however, the Netherlands Company controlled all the railways. When Cape Colony threatened to cut rates to prevent traffic being transferred to the Delagoa-Pretoria route, the Netherlands Company fixed the rates over the Transvaal section from Viljoens Drift, along which Cape traffic had to pass, at 8*d.* per ton per mile, compared with the average of 2·4*d.* charged by the Cape. This led to the off-loading of goods on to ox wagons at the frontier for road transport to the Rand, and to the 'drifts' crisis of 1895. The reopening of the drifts gave a temporary relief to the situation, but the railway war continued. Political alliances cut across economic interests, the Free State and the Cape railways competing with those of Natal and the Transvaal; the second group, with the aid of the prohibitive rate imposed on the terminal section, proved the stronger, and in 1897 the Delagoa Bay line carried 60 per cent. and Natal 15 per cent. more traffic to the Transvaal than in the previous year, while the Cape lines carried 30 per cent. less.¹ Natal's share then began in turn to decline, falling in 1898 by as much as 17 per cent. When the Anglo-Boer War began the Delagoa Bay line was depriving the Boer colonies of railway and customs revenues that were essential to their financial stability.

After the Anglo-Boer War the railways of the Netherlands Company were expropriated, a sum of £13,500,000 being paid for them, and the lines united with the railways of the Orange River Colony under the control of the Inter-Colonial Council. As the Transvaal had thus been made part owner of over 400 miles of the route to the Cape, it was hoped that the division of interests would be diminished. An agreement between the colonies was urgently required, both to remove the drawbacks of differential rates which still continued in operation, and to prepare for the programme of

¹ *Ibid.*, pp. 81, 85.

construction necessary in order to link the towns with agricultural and mining districts. But the Rand's dependence on native labour from Portuguese East Africa¹ stood in the way; the Transvaal had entered into a *modus vivendi* with the Portuguese Government in 1901 which preserved to Delagoa Bay its former preference in the matter of railway rates and customs duties, and the share of the Cape lines in the Rand traffic continued to fall. The solution was bound up with the settlement of the customs problem; in 1903, following a conference at Bloemfontein, the customs union was extended to include the four colonies, the High Commission Territories, and Southern Rhodesia, but there still remained the conflict of interests between the agricultural producer and the Rand and other urban consumers. The conflict centred on the system of preferential rates on colonial produce. To raise these rates to the level of those levied on imported goods would destroy the protection enjoyed by farmers, unless customs duties were proportionately increased, thereby raising the cost of living; on the other hand, to reduce the rates on imported goods would adversely affect railway revenues. These considerations, the continued loss by the Cape and Natal lines of traffic diverted to Delagoa Bay, and the severe economic depression which occurred after 1903 were responsible in greater or less degree for the continuation of the competitive struggle between the different railway groups. The rivalry led to a conference in 1908, which in the event dealt not with railway questions, but with the broader question of unification, thus opening the way to the National Convention of the same year.² The Portuguese *modus vivendi* of 1901 was replaced by the Transvaal-Mozambique Convention of 1909, which secured to Delagoa Bay from 50 to 55 per cent. of the Rand traffic; this arrangement was renewed in a new convention of 1928, but a subsequent agreement in 1934 reduced the proportion to 47·5 per cent.

The mileage of government lines had increased from 4,257 in 1902 to 6,989 at the time of Union.³ Much of the new construction had served to correct the longitudinal character which the railway system had assumed, as the result of the effort to connect ports and

¹ See Chap. XI, pp. 638-9.

³ *Official Year Book of the Union of South Africa*, No. 17, 1934-5, p. 720.

mining centres by the shortest route. The Cape built a line through the south-western districts to Port Elizabeth, and also opened up the sheep country farther on to East London; this, with other lines connecting the main systems and serving the agricultural districts, was the second stage in the history of railway transport, which continued after Union. The South Africa Act of 1909 vested all ports, harbours, and railways of the colonies in the Governor-General-in-Council; control was to be exercised through a board of three commissioners, appointed by the executive, with the Minister as chairman, but doubts as to the interpretation of this provision led to the passing of the Railway Board Act, 1916, which constituted the Board as an advisory body, and placed the general manager under the control of the Minister. There was at Union a formal separation of railway from general finance, which had previously been interdependent;¹ the South Africa Act further embodied (s. 127) the well-known provision that the railways and harbours should be 'administered on business principles, due regard being had to agricultural and industrial development within the Union'. Other measures providing that schemes of construction should be advised upon by the Board before submission to parliament, and that in certain cases losses on a line or services supplied at less than the cost were to be made good from Consolidated Revenue Fund, pointed to a desire to procure safeguards against the danger of the railways being monopolized by the claims of any one territorial or political interest. The institution of a separate Railway and Harbours Fund, from which only interest on invested capital could be transferred to Consolidated Revenue, limited the use of railways as a method of taxation.²

The construction of new branch lines into agricultural areas was continued after Union, the mileage of government lines being increased to 9,407 by the end of 1916. In 1922 the 1,330 miles of railway in South-West Africa was incorporated in the Union system. The building of branch lines, which had been almost suspended after 1916, was resumed, and 2,240 miles was added in the thirteen years 1923-35. In 1936 the Union and South-West Africa had a total mileage of 13,596, which included 680 miles of

¹ S. H. Frankel, *The Railway Policy of South Africa*, 1928, p. 79.

² See also, p. 1607, below.

private line, 597 miles being the Vryburg-Bulawayo section of the Rhodesian Railways. The total expenditure on the system of communications as a whole, including ports and steamships, has been £171,903,144. The mileage of open line per 1,000 square miles of territory is 17.32, as compared with 9.40 for Australia and 12.20 for Canada.¹ Under Act 30 of 1922 the Union has electrified sections of the Natal main line, and parts of the Cape Peninsular system; electrification is being carried out in the Witwatersrand area, which, when completed, will bring the mileage of electrified lines to 1,064 miles single track, perhaps the most extensive network of electrified railways in the British Empire.

(b) *The Rhodesias*

The Rhodesian railway system is owned by three companies: the Rhodesia Railways Ltd.,² the Beira Railway Co. Ltd., and the Shabani Railway Co. Ltd. Of the 2,708 miles of line constituting the whole system, 1,356 are in Southern and 643 in Northern Rhodesia, 399 in the Bechuanaland Protectorate, 112 in the Union, and 198 in Portuguese East Africa, all of which (apart from the Vryburg-Bulawayo section of 597 miles) is managed by a central organization at Bulawayo. The whole system owes its development mainly to the British South Africa Company,³ which assumed in the matter of railway transport the obligations which governments have had to accept in other territories; the company holds the majority of shares in the subsidiary concerns, but the relationship has introduced problems of a kind not usually associated with a state railway system.

Reference has already been made to the political factors which compelled the northern extension of the Cape Railway to abandon the direct route from Kimberley to the Transvaal, and to take the unpromising route through Bechuanaland;⁴ the line reached Vryburg in 1891, and was continued by the Bechuanaland Railway Company to Mafeking. The latter organization, which in 1899 had its name changed to the Rhodesia Railways, received an

¹ *Official Year Book of the Union of South Africa*, No. 18, 1937, p. 493.

² The Mashonaland Railway Co. Ltd. was absorbed by the Rhodesia Railways Ltd. in 1937.

⁴ See above, p. 1567.

annual subsidy of £10,000 for ten years, or half the amount promised to the Chartered Company by the British Government,¹ and land grants, amounting to 6,000 square miles, included in the 'railway strip'.² The funds for construction were provided by the issue of debentures with interest guaranteed by the Chartered Company.³ The line, which reached Bulawayo in 1897, was operated by the Cape Government under an agreement effected with the Chartered Company. Meanwhile the rival territorial claims of the British and Portuguese Governments in regard to Moçambique and the adjoining areas had been settled, as a result of the Convention of 1891 which gave the eastern coast-line to the Portuguese, but assured the Chartered Company of access to the sea by stipulating for the construction of a railway from Beira and the limitation of transit duty on British goods to a maximum of 3 per cent.⁴ A concession given by the Moçambique Company for the construction of the railway to the Rhodesian border was subsequently acquired by the Chartered Company, which in 1892 promoted the Beira Railway Company to construct a narrow-gauge line from Fontesvilla, 35½ miles from Beira, to Umtali. This was completed in 1898, two years after a line connecting Beira to Fontesvilla had been built by the Beira Junction Railway Company. The two Companies received blocks of land along the line, amounting to 130,673 and 28,290 hectares respectively;⁵ their capital was raised on debentures, in the issue of which the Chartered Company took a large share. The Mashonaland Railway Company, also financed by debentures guaranteed by the Chartered Company, took the line from Umtali to Salisbury in 1899.

Rhodes had contemplated that the south end of Lake Tanganyika would be the next stage on the way to Cairo, and in 1898 negotiated with the British Government regarding the project.⁶ He was, however, unsuccessful and the line was deflected farther west. Bulawayo was linked to Salisbury by the Mashonaland Railway Company in 1902, but it was from Bulawayo, and not from

⁶ Owen Letcher, *South Central Africa*, 1932, p. 133.

Salisbury, that the line continued its way to the north. The northern extension ran first to the coal fields at Wankie, and thence via Victoria Falls to Broken Hill, where zinc deposits had been found. Up to Kolomo construction was undertaken by the Rhodesia Railways, which received land grants of 801 square miles carrying mineral rights from the British South Africa Company, capital for construction being raised by a further series of debentures guaranteed by the latter company. From Kolomo to Broken Hill the line was built by the Mashonaland Railway Company;¹ this section was opened in 1906. A further section of 132 miles up to the Congo Border was completed in 1909 by the Rhodesia-Katanga Junction Railway Company, formed for the purpose by Sir Robert Williams, who, as explained elsewhere, had a share in the Katanga undertaking, and by Tanganyika Concessions Ltd., which had been formed to work it. It was acquired by the Rhodesian Railway system in 1928. In addition to the main railways, branch lines have been constructed to serve gold and other interests; two of them from Salisbury, one to Shamva and the other to Zawi, pass through good agricultural country. The bulk of European-owned land in Southern Rhodesia is situated within a zone of 25 miles from either side of the railway line;² the native reserves outside this region are badly served by railways.

It will have been observed that the capital for construction was raised largely by debentures guaranteed by the Chartered Company; the capital expenditure on the system up to 1924 is stated by General Hammond to have been £16,977,304, of which the debentures issued by Rhodesia Railways Ltd. and the Mashonaland Railway Company accounted for over £12,000,000.³ By 1911 the Chartered Company had advanced nearly £1,125,000 to the two companies in order to meet the shortfall on the debentures. It appeared at one time likely that, in view of these losses, the Chartered Company would have to face a scheme of reconstruction, but the railway returns subsequently improved and this step was not found necessary. In 1911 the Rhodesia

¹ *Report*, op. cit., C.S.R. 2, 1926, vol. i, pp. 9-10, 16.

² See Chap. XII, p. 819.

³ *Report*, op. cit., C.S.R. 2, 1926, vol. i, p. 5.

Railways Trust was created in order to take over the outstanding debts of the two companies; the outstanding obligations were gradually liquidated, but still stood at about £250,000 in 1936. At that date the outstanding capital of the whole system was £23,300,818, namely, Rhodesia Railways £12,389,003, Mashonaland Railways £8,805,500, Shabani Railway £304,165, and Beira Railway Company £1,802,150. The annual debt charges for debenture interest and the like were then £1,235,909.

After the grant of responsible government to Southern Rhodesia, an agreement was reached that led to the passing of the Railways Act, 1926, together with the Railway (Commission) Ordinance of 1927 in Northern Rhodesia and the Railway Proclamation (No. 8) of 1927 in Bechuanaland Protectorate. These statutes were replaced by legislation in 1935,¹ implementing a new agreement made in 1934, which did not, however, materially alter the system originally established. Under the legislation of 1927 a Railway Commission was set up, with members representing the three governments, and an independent chairman, to exercise certain functions of financial control, including decisions regarding the fixing or revising of rates, or the amounts to be carried to reserve. The law precludes such reductions in the schedule of charges as are calculated to reduce the total income when the amount standing to the credit of the reserve account is less than twice the loan provision; the Commission in 1936 remarked that proposals for rate reductions, unless compensated for by increased traffic, could not be considered favourably for some time to come.

General Hammond noted in 1926² that the railways were constructed as pioneer lines, planned to suit immediate needs, with little regard to traffic prospects along the route; he recommended the undertaking of route and traffic surveys, as part of a development programme intended to cover a period of years. In 1931 a general survey was carried out, with the aid of a grant from the Colonial Development Fund, in order to explore the possibility of constructing a line to connect the Rhodesia Railways with the South-West Africa system at Walvis Bay, a distance from Bulawayo

¹ Southern Rhodesia Railways Act, 1935; Northern Rhodesia Railways (Commission) Ordinance, 1935; Bechuanaland Protectorate Railway Proclamation, 1935.

² *Report*, op. cit., C.S.R. 2, 1926, vol. i, pp. 5, 81.

of 950 miles. While agricultural interests in Southern Rhodesia at one time strongly supported this line, as opening an alternative market to that of the Union, expert opinion¹ had found little justification for it, owing to the uncertainty whether the export of chilled meat, or the market for coal from Wankie, would be adequate to compensate for the almost complete lack of wayside traffic. These doubts would still seem to stand in the way of undertaking the very heavy expenditure which would be involved. Another proposal which has received consideration is that of constructing a line connecting Sinoia, north-west of Salisbury, to Kafue, south of Lusaka, a diversion which might reduce by 514 miles the distance taken by traffic coming down from the Congo. A survey of the suggested route in 1913 estimated the cost of construction as over £2,000,000;² but there is a general agreement that the extent of the traffic forthcoming would not justify its construction.

The rate of branch-line construction has been slow, the total mileage within Southern Rhodesia having increased in the period 1924-36 from 1,252 to 1,356, and in Northern Rhodesia from 506 to 643.³ In the latter territory the branch lines have been built mainly to serve the copper mines; the European farming community, as in the south, is settled for the most part in a zone on both sides of the railway, though a number of settlers, such as those in the Fort Jameson and Abercorn Districts, are remote from the line. There is little in the character of either European or native agricultural production which would appear to justify the construction of branch lines, and the probabilities of extension here, as in Southern Rhodesia, would appear to be dependent on the development of mining. An analysis of the figures of railway receipts shows that their movement corresponds very closely with the figures of mining production. There has been in the last two years a considerable rise in receipts; but the Rhodesian system has still to contend with the loss occasioned by the decline in coal traffic resulting from the reduction in the fuel requirements of the Belgian Congo mines, and the loss of part of their export of copper.

³ Ibid., p. 4, and General Manager's Report, 1936, p. 31.

There has at different times been a feeling expressed by producers that the rates are not fixed so as to secure the maximum development of the territories. The Hammond Report found¹ that the rates could not be said to have hindered the mining industry and were not excessive on the majority of agricultural exports, maize being the main exception, but on imports they were higher than elsewhere. The chief cause necessitating the maintenance of high import rates was the lack of traffic, but the employment of a high proportion of European workers, the numbers in 1936 being 3,631 Europeans to 11,197 natives and coloured,² also places a strain upon the resources of the railway. The average earnings of European railway artisans were found by the Railway Court of Enquiry, 1929,³ set up after the strike on the Rhodesian system, to approximate generally to the wage rates on the Union system, which is in a far better financial position than that of Rhodesia, and it would seem also that the railway artisan was at that time remunerated somewhat more highly than the engineering artisan in mining.⁴ The opening of the line to Lobito Bay and the completion of the rail-river connexion between the Katanga and Matadi has introduced a competitor for the Belgian traffic; but the Northern Rhodesia traffic is secured to the Rhodesian system by the mutual dependence of the coal and copper mines.

(c) *Nyasaland*

The Nyasaland railway system consists of 334 miles of 3½-foot-gauge line. In 1904 the Shire Highlands Railway Company began the construction of the first line, from Port Herald to Blantyre, a distance of 113 miles. Previously exports from Nyasaland were carried down the Shire and Zambesi rivers to Chinde, where they were transhipped into lighters and carried to Beira; the railway was intended to provide a better means of transport over the earlier part of the journey. Increasing difficulties of navigation led to the construction in 1915 of a further 65 miles of line, from Port Herald to Chindio, on the north bank of the Zambesi, by the Central African Railway Company, and in 1919 it was decided

¹ *Report*, op. cit., C.S.R. 2, 1926, vol. i, p. 52.

² General Manager's Report, 1936, p. 24.

⁴ *Report on Industrial Relations in Southern Rhodesia*, C.S.R. 3, 1930, paras. 90, 95.

to build the Trans-Zambesia Railway from Murraça, on the south bank of the Zambesi opposite Chindio, to join the Beira Railway at Dondo, 18 miles from Beira. The Trans-Zambesia line was constructed by means of £1,200,000 debentures at 6 per cent. guaranteed by the Nyasaland Government. The river fleets of the African Lakes Corporation and the British Central Africa Company were then purchased by the Trans-Zambesia Railway, partly to stop river competition, and partly in order to ferry traffic across the Zambesi between Chindio and Murraça; this purchase was financed by an issue of £200,000 ten-year notes at 5½ per cent. guaranteed by the Nyasaland Government. Railway connexion with the port at Beira, and with the Rhodesia-South African railway system through Dondo, was now complete, save for the crossing over the Zambesi between Chindio and Murraça. In 1926 General Hammond's Committee recommended the construction of a bridge to replace the Zambesi ferry; this bridge was completed in 1935 at a cost (including its approaches) of approximately £3,000,000. Meanwhile the line was extended north from Blantyre to Chipoka on Lake Nyasa at a cost of £882,441. For the purpose of carrying out these schemes the present Nyasaland Railways Ltd. was formed in 1930 with an authorized capital of £475,000; it acquired the debenture stock and shares of the Shire Highlands Railway Company which went into voluntary liquidation, and the greater part of the issued share capital of the Central African Railway Company, which became a private company. The Nyasaland Railways Ltd. financed the construction of the bridge and the extension to Lake Nyasa by means of advances from the Nyasaland Government, these advances being covered by income debenture stock. The Central African Railway and Trans-Zambesia Railway, in return for advances made to them by Nyasaland Railways Ltd., gave it income bonds secured on the earnings of the bridge and its approaches. The Nyasaland Railway Company is controlled by a board in London on which government is represented. The Imperial Government gave to the Nyasaland Government a series of interest-free loans, amounting to £1,500,000 in 1935-6, to assist in these operations; a certain portion of the Nyasaland public debt is also met by the Imperial Government.

With the completion of the line northwards the more productive areas of Nyasaland have been brought within reasonably direct railway or lake communication with Beira, though, as has been seen, this has been effected at the cost of a heavy obligation on the part of the Imperial and Nyasaland Governments for the payment of interest charges. The receipts of the Nyasaland Railways Ltd. amounted in 1937 to £193,000; the railway depends largely on its import and not on its export traffic, the latter in 1937 accounting only for £58,000. So far receipts have not been sufficient to pay interest on the share capital.

(d) *Tanganyika Territory*

The railway system of Tanganyika consists of the Central Railway from Dar-es-Salaam to Kigoma on Lake Tanganyika, 773 miles, with branch lines from Tabora to Mwanza on Lake Victoria, 235 miles, and from Manyoni to Kinyangiri, 93 miles, and the Northern Railway from Tanga to Arusha, 273 miles. The Central and Northern lines are not connected except by road; both are metre gauge. In 1904 the Germans gave a concession to a company with a capital of £1,000,000, towards which the German Government was chief subscriber, for the construction of the Central Railway; it reached Lake Tanganyika early in 1914, following the old Arab trade route through much sparsely populated and fly-infested country. Earthworks on the branch line from Tabora to Mwanza were started by the German company before the War; the present line was laid in 1925 and opened in 1928; it taps a fertile area producing groundnuts and cotton. The branch line from Manyoni was begun in 1930 and completed in 1933. The first part of the Tanga (or Northern) Railway was constructed by a company taken over by the German Government in 1899; it was extended for political reasons, reaching Moshi in 1911. Plans for an extension to Arusha were drawn up by the Germans, but were not put into effect by them; the Tanganyika Government began construction of the remaining portion in 1927, and the line was opened in 1929. The Voi-Kahe branch line, which forms a connexion between the Northern line and the Kenya-Uganda Railways, was constructed for military use during the War. The value of the German lines as taken over by the

mandatory government was estimated at £4,894,050, for which a sum of £34,000 was paid to certain claim-holders;¹ but both the Northern and Central lines were extensively damaged during the War by the German forces, and an expensive programme of development and repairs was required when funds became available. As has been seen, all the lines are owned by the Tanganyika administration; a Railway Council of four official and four non-official members has been appointed to advise on questions of policy. The railways, the finances of which are now being separated from general revenues, represent a capital charge of over £5,000,000. For the five years preceding 1936 there were annual deficits in their working, and their liability to the territory, including borrowings from treasury funds, amounted in 1936 to £452,131; in addition £413,049, representing the deficiencies during 1919-21, are excluded from the accounts, being only repayable should the railways become a separate entity; any question of repayment of a further £449,505, advanced by the Imperial Exchequer to meet deficiencies between 1921 and 1926, is deferred until 1938. In 1936 the railways showed a surplus of £52,875, and in 1937 there was a surplus of £83,198. Further development is to be financed from a railways renewal fund; repayment of an advance to this fund from general revenue absorbed £50,000 of the 1936 surplus, and another £50,000 was paid into it out of the 1937 profits. From the 1937 surplus £591 has also been found to finance capital works, leaving a net surplus of £32,607 for the year, which will reduce the accumulated deficit to £175,703. Although a surplus of about £36,000 is estimated for 1938, the financial position remains insecure; no provision has been made for wasting assets, and the position is not one in which a reduction of rates could be safely contemplated. The source from which the railways draw their revenue is now limited to local traffic; since 1931 a considerable part of the Belgian copper freight has been diverted from Dar-es-Salaam to Lobito Bay; in that year the copper freight amounted to 50 per cent. of the value of the freight carried.

The extension of the Central Railway to Mwanza brought it

¹ Article 257 of the Peace Treaty, which provided that the mandatory should not be charged with any portion of the debt of the German Empire or states, has been interpreted to imply that the mandatory is not responsible for the obligations incurred by German companies or the German Government on account of this or similar railways.

into competition with the Kenya and Uganda Railways for the trade of the southern portion of the basin of Lake Victoria, which had hitherto been collected by the steamers and lighters of the latter railways for dispatch from Kisumu. Other interests were also involved, notably those of the firms using Mombasa and Dar-es-Salaam respectively as ports of export. The Secretary of State ruled in 1928 that non-competitive rates should be arranged, leaving trade to take its natural course, a decision implemented by an agreement permitting the Kenya-Uganda Railways to retain their lake traffic at all points except Mwanza; the rates from Mwanza to either Dar-es-Salaam or Mombasa were to be equalized, and the rates from Tanganyika ports across the lake were made higher via the Tanganyika route than via Kenya by the cost of transport across the lake. It has been contended by Tanganyika interests that this arrangement still left certain advantages with the Kenya-Uganda Railways, derived, among other causes, from their ownership of the steamers on the lake. In the course of an official inquiry made by Mr. R. Gibb in 1932,¹ it was suggested that the traffic arising at, or destined for, Tanganyika ports on the lake should be pooled to prevent undue competition, and that as regards new traffic a contribution should be made by the Kenya and Uganda Railways to the Tanganyika Railway for tonnage in excess of an agreed proportion. In 1934 the Secretary of State decided against a change in the previous arrangement until the total traffic to the Tanganyika lake ports reached the figure of the tonnage handled by the Kenya and Uganda Railways prior to the building of the Mwanza line; this figure was exceeded in 1935, but Sir Osborne Mance, who reported on the matter as the result of a special inquiry made in 1936, expressed the view that it would be preferable to revert to the decision of 1928, and allow the routes to function in accordance with their relative advantages; he considered that the present rates on the Kenya-Uganda system with Mombasa should apply equally to Dar-es-Salaam for all Tanganyika ports, the revenue from traffic being pooled and divided on a percentage basis.² The settle-

¹ R. Gibb, *Report on Railway Rates and Finance in Kenya, Uganda, and Tanganyika*, Cmd. 4235, 1933, p. 52.

² Brigadier-General Sir H. O. Mance, *Report*, op. cit., pp. 49-55.

ment finally arrived at in 1937 provides for equality of rates, freedom of choice by the trader, payment to the transport systems for services rendered, and a division of profits between the two railways. It is estimated that the first year of operation of the agreement will result in a payment by the Kenya and Uganda Railways to the Tanganyika Railways of about £5,000.¹

The Northern (or Tanga) line, owing to the Voi-Kahe connexion, also brings the interests of the Tanganyika Railways into touch with those of the Kenya-Uganda system; it is able to divert to Mombasa the traffic from the coffee- and sisal-growing area of Kilimanjaro and Moshi. Suggestions which have been made either to close the connecting line with Kenya to reduce losses, or to hand it over to the Kenya Government,² have not been carried out, but the question appears of recent years to have lost some of the importance which once attached to it. The rates from Moshi to Mombasa are assimilated. Sir Oswald Mance's report suggests that a pooling arrangement on the principle suggested for the Lake Victoria traffic would be likely to give the Tanganyika Railways a fair share of profits and traffic.³ The Commission on Closer Union in East Africa expressed views in favour of a united control of the railway systems of the two territories in order to avoid competition between the ports as well as the railways.⁴ There are, however, obvious difficulties of a political nature in such an arrangement, so long as the two territories are not united in any form of federation. In 1933 the Conference of East African Governors recommended the formation of an East African Transport Policy Board, and the Secretary of State decided that the Governors' Conference itself should exercise the functions of the Board in order to discuss questions of policy affecting Kenya, Uganda, and Tanganyika.

It is noteworthy that 56 per cent. of the engine drivers and 65 per cent. of the employees in the Engineering Department are Africans.

(e) Kenya and Uganda

The Kenya and Uganda railway system consists of the main line from Mombasa to Kampala, 879 miles, with a connexion to Kisumu, 131 miles, to Soroti, 100 miles, serving the Eastern Uganda cotton districts, and from Voi to Kahe, 92 miles, to connect with the Tanganyika Railways. There are seven minor branch lines, with a mileage of 329 miles, and in addition a private line of 91 miles serving the soda deposits at Lake Magadi. The lines are metre gauge, a fact due to their having been constructed in the first instance by Indian engineers and fitted with rolling stock from India. The original construction of the railway was accepted as essential to the establishment of an effective protectorate over Uganda, partly as assisting in the suppression of the slave trade, partly for strategic reasons; in 1896 parliament approved a preliminary expenditure of £3,000,000 and in 1900 an additional £2,000,000, without any estimate of the prospects of a commercial nature which the line might possess. The ultimate cost of the railway in the first period of construction was £5,502,592; the liability for the payment, or payment of interest, is recognized; Sir Alan Pim has, however, given the opinion that the finances of Kenya should be relieved of this prospect of a heavy service of debt in connexion with the loan. The question has been deferred and will come under review during the year 1938.¹ The line was completed as far as Kisumu in 1901; the total mileage at the end of 1915 was 777 miles. With the exception of the Voi line, built for military purposes during the War, development ceased until 1922, when a period of expansion again set in, and, as has been shown, the lines now have a mileage of 1,622.

The Kenya and Uganda Railways are administered as a government department of Kenya with a General Manager in charge. Difficulties arose early regarding the respective interests of Kenya and Uganda in the railway; these came to a head in 1918 when Kenya (which at that time received credit for the whole of the net revenue from the line) placed a surcharge, followed in 1919 by a supercharge, on traffic rates in order to meet a deficit in its general

¹ *Report on the Financial Position and System of Taxation of Kenya*, Colonial 116, 1936, p. 243.

revenues.¹ As a result, the Kenya and Uganda (Transport) Order in Council of 1925 created the post of a High Commissioner of Transport, with a Railway Advisory Council of four official and four non-official members from the two territories, to deal with matters of estimates, rates, fares, and extraordinary expenditure; the High Commissioner was to be the Governor of either Kenya or Uganda; the expenditure of the railway and other transport services was to be separated from general revenues, and placed to a railway and harbour account. Mr. Gibb reported in 1933 that local pressure and influence were brought to bear upon management and construction, and that the ruling policy of cheap export rates, high import rates, and differentiated rates in favour of locally produced commodities² was inspired by political considerations rather than sound railway economics. He suggested that the authority of the Advisory Council should be abolished and a small London board be formed to act as a corrective to local interests. In order to secure the complete separation of railway from general policy, he suggested forming a company on the lines of the Nyasaland Railway Company, so that future financing could be carried out by the Company, the two governments concerned holding rights proportionate to their interests.³ These recommendations have not, however, been accepted.

The finances of the railways have an important bearing on the budgetary position of Kenya. The expenditure on capital account at the end of 1936 amounted to £21,999,072; of this £8,074,966, including the £5,502,592 mentioned above, is free of interest, being derived from non-interest-bearing loans or revenue sources; the interest on the balance is guaranteed by the respective governments in the proportions of £13,045,343 by Kenya and £878,763 by Uganda, though it is also stated that Uganda accepts responsibility for £2,000,000 out of the former sum, representing assets constructed in Uganda. In 1935 the surplus on the railways and allied services was £362,772,⁴ of which £319,161 was paid into a reserve account; the balance of the renewals and other funds at the end of 1935 was £2,483,867. The railway is primarily a goods,

¹ See *Report of the Uganda Development Commission*, 1920, p. 10.

² See further on this point, Chap. XX, p. 1391.

³ R. Gibb, *Report*, op. cit., pp. 43-4.

⁴ In 1937 it was £584,326.

not a passenger, line, and rates have been adjusted to enable the principal crops of cotton from Uganda, and maize and coffee from Kenya, to be exported as economically as possible; it is therefore the policy to counterbalance low export rates, particularly on maize from Kenya and cotton from Uganda, by high import rates, these being based on a taper rate which increases by diminishing amounts as the distance increases. The arrangement is one which has been criticized in Uganda, where it is contended that the native protectorate is helping to subsidize the export of European-grown maize from Kenya. Preferential rates also exist for goods grown or manufactured locally, and this, so far as Kenya is concerned, acts as a form of tariff protection at the expense of railway finances. Apart, however, from these considerations the high rates charged on the railway, which appear to be necessary in order to meet the loan charges, amounting in 1936 to £850,100, are undoubtedly a serious handicap to the development of Kenya. The handicap would be further increased were interest to be charged by the Imperial Treasury on any considerable part of the interest-free debt. But for this consideration the position of the railways is sound, since they are able to present a surplus after contributing to a sinking fund as well as to a renewals fund; in this latter respect the finance of the railway is at a disadvantage compared with that of a private undertaking.

(f) *Nigeria*

The Nigerian railway system has a total length of 1,900 miles, and for administrative purposes is divided into the Western, Northern, and Eastern Districts. The Western and Northern Districts main line runs from Lagos to N'guru, 843 miles; there are three branch lines with a mileage of 275 miles, and a 2½-foot-gauge line of 133 miles from Zaria to the tin-mining plateau of Jos connects with the main line from Port Harcourt. The construction of the system was begun in 1898, a short line being built from Lagos to tap the local agricultural and forest products; the second line began inland at Baro to connect Kano with the river Niger; the line from Lagos was then extended to the Niger at Jebba, and, as river transport became inadequate, the railway was continued through an uninhabited belt to join the Kano-Baro line at

Minna; deposits of tin were then found on the Bauchi plateau and the Zaria-Jos Railway was constructed. The Eastern District main line runs from Port Harcourt, joins with the Western line at Kaduna, 569 miles, and has a branch line of 63 miles, completed in 1927, connecting with the Zaria-Jos line; a bridge of considerable length crosses the Benue at Makurdi. With the exception of the Zaria-Jos branch line the gauge throughout is 3 feet 6 inches. It will be seen that there are three routes for produce from the north to the sea—by rail to the two ports, Lagos and Port Harcourt, and by river transport on the Niger; the Minna-Baro line by tapping the Niger river forms a problem of rail versus river transport by allowing produce to be brought down by rail to the Niger and thence forwarded by a private river transport company. This section of railway was hastily constructed and is at present worked under restricted conditions, its future being uncertain.

The railway system belongs to the state. The total capital expenditure was £22,950,856 in 1936, of which £19,993,437 was loan capital; the annual interest charge was £1,048,729. In 1929-30 there was a surplus, which was paid into the general revenues; in the years 1930-5 there were deficits amounting to £956,923, though no provision was made for renewals; the receipts allowed no adequate provision to be made for renewals in 1935-6. There is no doubt that the railway, which had not had the benefit of any interest-free loan, had become by this time a heavy charge on the general revenues of the territory; the bulk of its traffic was low-rate produce, and the eastern section, between Kaduna and Enugu, showed in particular a heavy deficit which had to be carried by the system as a whole. In 1936 it was decided to reorganize the system as far as possible on commercial lines; the Enugu-Kafanchan section was classed as a development project, and the finances of the railway system were relieved of its interest charges. For the future, railway deficits will be met by loans from government funds at rates of interest to be fixed at the time when they are taken, the interest on existing loans having been reduced to 3 per cent.; the total sum at charge on capital account has been adjusted in accordance with the report of a committee appointed in 1934 to deal with the question of wasting assets.¹ The railway will now

¹ *Memorandum on the Nigerian Government Railway Estimates for 1936-37*, Jan. 1936.

be self-contained in the matter of finance, and will, if possible, build up its own reserve fund to meet losses such as those which have in the past followed on the failure of a main export crop. A sessional paper, No. 12 of 1935, recommended that the state services of railways, marine, colliery, and ports be fused into one commercialized department; it has, however, been decided not to attempt a full fusion, but to create a Director of Transport who will also be Chairman of a Transport Advisory Board. It is estimated that the railways have lost largely from road-transport competition in the coastal areas, and the eastern section is also affected by the existence of ports unconnected with the railway. Taking the position as a whole, it may be said that though the position regarding the railways has been clarified, their position is still insecure; the trade of the territory has not yet developed up to the transport capacity of its railways.

(g) *The Gold Coast*

The Gold Coast railways consist of two main lines from the coast to Kumasi, that from Takoradi having a mileage of 173 miles, and that from Accra 193 miles; there are five branch lines with a mileage of 134 miles. Except for the 10 miles of the Weija branch line, which is of 2½-foot gauge, the lines are of 3½-foot gauge. Construction was begun from Sekondi in 1898, largely as the result of the gold-mining activity at Tarkwa, but it was not completed to Tarkwa until 1901 owing to labour difficulties and the last Ashanti war; Obuasi, the head-quarters of the Ashanti gold fields, was reached in 1902, and Kumasi in 1903. The line from Accra was begun in 1909, but for various reasons did not reach Kumasi till 1923. Owing to constructional difficulties, and the high price of materials immediately after the War, the capital cost of the railway stood in 1936-7 at the high figure of £9,354,139; about £1,479,936 was provided from government funds, free of interest, but the loan charges on the remainder constitute on an average about 36 per cent. of the gross annual railway expenditure. The railway is organized as a government department with a general manager; it is of interest to note that the European staff in 1936-7 was 101, African clerks were 570, and African drivers and semi-skilled employees 1,291. The revenue of

the railways is principally derived from the transport of cocoa and manganese ore for export, and is subject to fluctuations with the market demand for these two articles: it fell, for instance, from £1,242,947 in 1928-9 to £683,103 in 1932-3. Between 1929-30 and 1934-5 the annual working showed a deficit; in 1935-6 it showed a surplus of £35,983, partly owing to the successful cocoa crop, the increase in manganese-ore exportation, and extended gold-mining activity, and partly to a reconsideration of policy in regard to rates and fares. In 1936-7 the surplus was £115,633. The reduction in the fares has led to a large increase in third-class travel.

(h) *Sierra Leone*

The main line of the state railway runs 227 miles from Freetown to Pendembu, a trading centre near the boundaries of Liberia and French Guinea; a branch line of 104 miles from Boia to Kamabai serves the Northern Province. The construction of the main line was begun in 1896, but it did not reach Pendembu till 1908. The capital expenditure at the end of 1936 stood at £1,428,243, of which £382,743 was obtained from general revenues, free of interest. The gauge throughout the system is 2 feet 6 inches; a feature of the system is the large number of bridges, totalling 43 with two spans or more. In 1927 the railway finance was separated from general revenues, and organized as a self-contained account; but the railway has constantly been unable to meet its charges for interest, and from 1899 to 1935 general revenues had to make a contribution of £1,927,044 on this account. In 1936 there was a small surplus. The railway is, however, dependent on the export of the one principal commodity of palm kernels, and the state of its finances is liable to be seriously affected by the contraction of overseas markets; heavy expenditure on renewals is estimated to fall due in 1940, and as there is no renewals fund the government will presumably be called upon to make special provision for it. A subsidy of 15s. per ton conveyed is paid out of general revenue as a contribution in consideration of a special reduction in the railway rate for palm kernels. A railway of 3½-foot gauge, owned by the Sierra Leone Development Company, connects the iron-ore deposit at Marampa with a port at Pepel, a distance of about 50 miles.

(i) *French West Africa*

The railway system in Senegal consists of the Dakar-Niger main line from Dakar to Koulikoro, 1,219 km., with 70 km. of branch lines; another main line, the 'groundnut' line, follows the coast from Dakar to St. Louis, 263 km., with a branch line to Linguère of 128 km. In French Guinea a main line of 662 km. runs from Conakry to Kankan; in the Ivory Coast a main line runs north to Dioulasso, 796 km.; in Dahomey a main line, the *Central-Dahoméén*, runs to Parakou, 437 km., with branch lines of 143 km.; there are other short small-gauge branch lines totalling 111 km. Construction of the Kayes to Koulikoro section of the main Dakar-Niger line was begun in 1881 to unite the Senegal and Niger rivers; owing to the difficulties encountered it was not completed to Koulikoro until 1906. The section to Thiès, to connect the Sudan with the sea, was finished in 1924; the branch to Kaolack, a port on the Saloum river, shortens the route for shipment of goods by sea by 185 km. The Dakar-St. Louis Railway, which was opened in 1885, was constructed by a concessionary company, and includes the Dakar-Thiès section of the main line. Construction of the Conakry-Kankan line began in 1900, and was completed in 1914; by affording a quicker communication between the Niger and the sea it has diverted traffic from the Dakar-Niger route. The Ivory Coast Railway was begun in 1903, but owing to tribal insurrections and other troubles it only recently arrived at its present terminus. The *Central-Dahoméén* Railway was constructed in 1900 by a concessionary company, from which it was bought by the government in 1930.¹ In 1931 the total length of the railways was 3,426 km., by 1936 this had increased to 3,804 km.² It may be doubted whether the scheme for constructing a Trans-Saharan line will ever come to fruition; its value would be almost entirely military, as enabling troops raised in the West African colonies to take a land route to Algiers. The scheme involves a line from Reggan which after crossing the Sahara would divide into two branches, one to join with the Senegal system via Koulikoro and the Ivory Coast line

¹ *Le gouvernement général de l'Afrique occidentale française*, 1931, pp. 124-36.

² *Annuaire statistique de l'Afrique occidentale française*, 1934-5-6, pp. 52, 154.

via Bobo-Dioulasso, and the other proceeding via Gao and Niamey to join with the Dahomey line.

The railway systems of French West Africa are designed, so far as part of the territory is concerned, as part of a joint river-rail system, and have of late years been developed largely to provide as cheap transport as possible in the interests of the policy of *mise en valeur*. The amount of capital invested in the West Africa system has been estimated at £11,100,000; but it cannot be said to present a self-contained account, in respect either of the statement of the capital at charge, or the amount of interest payable, or the provision made for renewals. It is not therefore possible to check the statements which are from time to time made that these railways are remunerative. In the mandated territory of French Togo three railways of metre gauge run from the Port of Lomé, namely, to Anécho, 44 km.; to Palimé, 119 km.; and to Blitta, 280 km. The first two lines were constructed by the Germans between 1905 and 1907, and the Blitta line was taken in 1911 as far as Atakhamé; the remaining section was constructed by the French in 1934 at a cost of 110,000,000 francs.¹ The railways are owned and administered by the government; in 1936 the railway administration was brought under that of the Dahomey system, but the administrations have again been separated.

(j) *French Equatorial Africa*

In the French Congo a state railway line of metre gauge runs from Brazzaville on the Congo river to Pointe Noire, a distance of 560 km. The exports from the Middle Congo Province of Equatorial Africa had previously been dependent on the Belgian railway, Kinshasa-Matadi, and the use of the Belgian port; apart from any political considerations, there was a habitual state of congestion on the railway. But the difficulties of constructing an alternative route through the Crystal Mountains were very great.² Some 3,500,000 francs was spent on preliminary surveys after the project was first formed in 1886;³ construction only began in 1922 and was not completed until 1934, at a total cost of 930,000,000

¹ *Rapport annuel au Conseil de la Société des Nations sur l'administration du Togo pour l'année 1934*, pp. 20-49.

² W. Fitzgerald, *op. cit.*, 1934, pp. 295-8.

³ M. Sarraut, *La mise en valeur des colonies françaises*, 1923, p. 421.

francs.¹ The *Société de Construction des Batignolles*, which had the contract for construction, had great difficulty in securing labour, and an *arrêté* of the Governor-General distributed over the different provinces the quota of labour to be supplied, on a system which amounted in effect to compulsory recruitment.² Health conditions were inadequately safeguarded, and it is said that 15,000 to 18,000 natives died during the construction, the mortality being 45·20 per cent. in 1927 and 17·14 per cent. in 1929. The railway has been described, from the economic point of view, as 'une absurdité et un désastre'.³ It is not easy to determine how far this stricture is justified; in 1933 the line was stated to have shown a profit of 239,762 francs, but in the absence of any account of the capital position of the railway and its interest obligations it is difficult to accept this surplus as real.

The Cameroons under French Mandate is served by two metre-gauge railway lines, the North line from Banabéri to N'kong-samba, 160 km., and the Central line from Douala to Yaoundé, 308 km., with a branch line joining Otelé to Mbalmayo on the navigable Nyong river, which was changed from 60 centimetre to metre gauge in 1936. The Germans began the construction of the Central line in 1910; M. Sarraut alleges that it was part of a scheme for a transcontinental line to Dar-es-Salaam.⁴ The statement has been made that the Germans expended about £4,000,000 on the railways taken over by the French in Togo and the Cameroons; as in the case of Tanganyika, nothing was paid by the mandatory on this account.⁵ When the French occupied the country the Central line had been made for a distance of 181 km.; by 1927 it had been continued to Yaoundé, trouble having in the meanwhile been encountered in securing labour other than by forced recruitment. The Northern line has not been extended since the French occupation, but a commission appointed by the Minister for Colonies in 1930 proposed the extension of the system from Yaoundé to Kaita on the Logone river and thence branching to Fort-Archimbault and to Maroua. The cost of the

⁵ Minutes of Ninth Session, Permanent Mandates Commission, 1928.

1,675 km. of line involved is estimated at 1,200,000,000 francs. The railways are owned and managed by the administration; the cost of the construction undertaken by the French was less than 300,000 francs per kilometre, and the expenditure on the main lines was met from general revenues; the reconstruction of the branch line was financed from a loan for the general development of the territory. The railway is in consequence treated as free from interest charges, and the rates for passengers and for goods are kept at a low level; in 1921 a reserve fund was formed, financed from profits. Except in 1931 the railway has in recent years shown a profit.

(k) *Belgian Congo*

The railway system of the Belgian Congo was primarily designed, in the words of the resolution of the Berlin Convention of 1885, 'dans le but spécial de suppléer à l'innavigabilité ou aux imperfections de la voie fluviale sur certaines sections du Congo'; but of late years there has been a tendency to give increasing importance to the railways, which, with the motor roads, are becoming the arterial lines, with the rivers taking more and more the position of 'feeders'.¹

As the mineral resources in the north-east and the south of the country began to assume importance, both political and economic considerations demanded attention to the development of communications with the Congo port of Matadi. The basis of the present system of communications is the Matadi-Léopoldville Railway,² and the two axes to tap the gold-mining areas in the north-east region, and the copper deposits in the southern Katanga, are being formed by lines of communication, starting from Léopoldville, which combine river and rail transport. On the first axis the Congo river will continue to provide the main line of transport from Léopoldville to Stanleyville. From Stanleyville a mixed line of river and rail transport already exists via Kindu, Kongolo, and Kabalo up to Albertville on Lake Tanganyika. But a Congo-Nile Railway has also been projected, which, taking off from

¹ W. Fitzgerald, *op. cit.*, p. 296.

² The railway is sometimes known as Kinshasa-Matadi; Kinshasa is the industrial town, Léopoldville the administrative.

Stanleyville, will turn north-east to serve the Kilo-Moto gold mines, and then proceed to Kasenyi on Lake Albert, thus coming into contact with British East Africa through Butiaba, on the east shore of the lake, and with the Nile system through the Albert Nile and Nimule. The second axis based on Léopoldville is formed by the Kasai river route to Port Francqui, whence the Bas-Congo-Katanga line, known as the B.C.K., runs south-east to Tenke (where a connexion runs west to join the Lobito Bay Railway near Dilolo on the Angola border) and then proceeds through the Katanga copper fields to link up with the Rhodesian Railway system at Sakania, a short distance below Élisabethville. A railway has also been projected to join Léopoldville and Port Francqui, thus accelerating transport by substituting a rail route for the steamer route on the Kasai. The number of river crossings would make the scheme very costly.

The railway system covered in 1935 a total distance of 4,788 km. Shown in detail, it consists of the *Chemin de Fer du Mayumbe* from Boma to Tshela, 140 km., constructed between 1900 and 1903; the *Chemin de Fer du Congo*, 400 km., from Matadi to Léopoldville, partly constructed between 1890 and 1898, and reconstructed and completed in 1929;¹ the *Chemins de Fer du Congo Supérieur aux Grands Lacs Africains*, 125 km., from Stanleyville to Ponthierville, finished in 1906, with a further 355 km., from Kindu to Kongolo, built 1906 to 1910, and 273 km., from Kabalo to Albertville, completed in 1915; the *Chemin de Fer du Bas-Congo au Katanga* (the B.C.K.), from Port Francqui to Sakania, 1,836 km., constructed between 1909 and 1931, with a branch 520 km. long, starting at Tenké and forming the connexion with Dilolo on the Angola border; the *Chemins de Fer Vicinaux du Congo*, 715 km., of 60 cm. gauge, from Bondo, on a navigable branch of the Congo, to Paulis, completed in 1934; and a short line of 93 km. which assists traffic between Lakes Tanganyika and Kivu.

The railways have been constructed and are maintained with the active participation of the government. In the case of the Matadi-Léopoldville line the state, besides making an original

¹ To secure the necessary land for this reconstruction Belgium exchanged in 1927 a small area of land near Dilolo on the Angola border (the 'Dilolo Boot') for 3 sq. km. near Matadi.

grant of 100,000 hectares of land, assisted in providing capital, but otherwise allowed freedom in construction and exploitation. In other cases the state has carried out the construction and retained an interest in finance and management, as in the instance of the *Chemins de Fer du Congo Supérieur aux Grands Lacs Africains*, or has formed a company in which the state holds the majority of the shares, as is the case with the *Chemin de Fer du Bas-Congo au Katanga*. Since 1928 the assistance given has been mainly by government guarantees of interest. Only two small local lines are run by companies without the financial assistance of the state. Besides the *Compagnie du Chemin de Fer du Congo* which holds the Matadi-Léopoldville concession and has received a grant of over a million hectares, known as the Bus-Block, other railway companies have also had large grants of land. In more than one case railways, after importing labour from French West Africa and Nigeria, found it necessary to apply for state assistance in impressing local labour, and large forces of workers were thus secured for them. As in the case of labour impressed elsewhere for similar purposes, there was a high incidence of disease and mortality amongst them.¹ The gauges of the railways vary from 0 m. 60 to 1 m. 067, but through-connexion with the Rhodesian system has necessitated construction of the Bas-Congo-Katanga lines on the South Africa standard basis of 3 feet 6 inches, and future construction will only be authorized by the state in this gauge for main lines or in the 60-cm. gauge for secondary lines.

It would appear that about up to 1932 some £38,000,000 was invested in Congo railways, and in addition the colony had advanced approximately £2,300,000 from revenue. The published figures do not provide material for determining the exact nature of the financial return on the capital invested; it is known, however, that of the guaranteed railways the *Chemin de Fer du Katanga* is the only one which has never called on the state to pay up its guarantee; and the matter is complicated by the fact that in addition to its guarantee the state has bound itself in some cases to pay direct subsidies in order to lower the rates for freight. Reports of the Colonial Commission of the Belgian senate constantly refer to the losses incurred; the result in their opinion

¹ See above, p. 1590, and Chap. XI, p. 614.

is that development has been hampered by high rates on freight, while the colony has suffered direct losses under its guarantee which it could have avoided under a system of state construction and management. The difficulties arising from the present system were felt with especial force during the depression; in 1932 the interest and amortization charges amounted to 340,000,000 francs, or 165 per cent. of the total receipts of the railways. In view of the inter-dependence of the river, railway, and land systems of the Congo, a government *Comité Permanent de Co-ordination des Transports au Congo* was instituted in 1929, composed of heads of the public utility companies and government representatives, in order to consider common transport problems. It appears to have been of assistance to commerce in securing some greater uniformity of tariffs, but the major financial problems arising from the connexion between the state and the railway companies will require a more radical treatment for their solution.

(1) *The Portuguese Territories*

The state railway system of Angola includes the line from the port of Loanda to Malange, 426 km. with branch lines of 184 km., also a line of 106 km. from Port Amboim to Chindinde. About £2,000,000 appears to have been invested in this system and in expenditure on the ports. It taps a good maize, sisal, and coffee region, but the traffic results are said to have so far been disappointing.

Angola has in addition the length of the Benguela Railway between the port of Lobito and Dilolo on the Angola-Congo border. The construction of the Benguela line occasioned at one time an international interest not unlike that aroused by the scheme for a Baghdad railway. In 1900 Portugal had given a concession for the construction of a railway running from Lobito Bay to the central Angola plateau, which appeared to be well suited for European colonization, and by about 1912 a mileage of some 560 km. had been constructed. The most prominent part in the promotion of the scheme was taken by Sir Robert Williams and Tanganyika Concessions Ltd.; the former, as shown elsewhere, had received in 1900 a concession from King Leopold II to exploit the Katanga area. He had formed Tanganyika Concessions Ltd., and

the latter subsequently held a share in the *Union Minière*, created in 1906 to operate the copper mines. It would not appear that the Belgian authorities were in the first instance impressed with the value of connecting the Benguela Railway with the Katanga, since, though it offered them a route to the sea which is shorter by 600 miles than that to Beira, it would compete with the connexion between Matadi, Port Francqui, and the Bas-Congo-Katanga line which they desired to see developed. But about 1913 they agreed with the Portuguese Government that the Benguela Railway should be continued to the Katanga. The capital of the Benguela Railway Company, which stood at about £3,000,000, was insufficient for the purpose, and the attempt to raise fresh capital involved negotiations in which Germany finally took a share. They formed a part of the incidents which had their issue in the secret convention between Germany and Great Britain demarcating their respective spheres of interest in the Portuguese African possessions; the convention seemed to contemplate that in certain circumstances the two powers might move towards occupation of these spheres. The War put an end to any prospect that Germany might share in the Benguela Railway, and when the proposals for the suggested extension were subsequently renewed, an application was made by Tanganyika Concessions for assistance under the British Trade Facilities Act of 1921. At that time Tanganyika Concessions held five-sixths of the shares in the Benguela Company and Portugal the remainder. There was at first some opposition by South Africa to the grant of the loan, in the interests of the Rhodesian Railways, but in 1925 the Trade Facilities Committee agreed to advance £1,250,000 to the Company. The Benguela Railway was completed in 1929, the Belgian Government having made itself responsible for the connexion between Dilolo in Angola and Tenke on the Bas-Congo-Katanga Railway, a distance of about 520 km., this section being completed in 1931.¹ The length of the railway in Portuguese territory is 1,347 km. It is stated that the total cost, including the Lobito Bay port, has been approximately £13,000,000. The greater part of this has been provided by British capital. The railway plays an important part in the policy of colonial reorganization promoted by the government of Dr. Salazar, which attaches

¹ 'The Benguela Railway', *The African World*, June 1935, pp. 36-8.

special value to the development of Angola, hitherto the most neglected of the Portuguese possessions, and to the colonization of the central plateau. The railway company has made a beginning on a small scale in a scheme of assisted colonization; and the population of Nova Lisboa, the railway centre, has lately increased from 1,000 to 5,000. But, as has been shown, the railway receives only part of the production of the Katanga for transport to Lobito Bay, and the general results have so far been disappointing.

In East Africa the state has invested about £6,600,000 in railways, and in addition the Beira Railways and the Trans-Zambesia lines have been built with British capital. The railway system in Moçambique covers approximately 861 miles. The line which runs for 89 km. from Lourenço Marques to join the South African Railways at Ressano Garcia on the Transvaal border is the most important, and has profited greatly from the fact that Lourenço Marques is the port of entry for the gold fields. A line running from Lourenço Marques to Goba on the border of Swaziland and intended to be linked with the Union system is of minor value, since the Union system has not entered Swaziland, which, as has been shown, is served only by a motor service. Another line runs from the port of Moçambique to Ribaué and is intended to form a connexion with the Nyasaland border; it has for the present stopped at about 280 km. from the port. The year 1934 showed a surplus of £423,331 on the Moçambique system; nearly a million tons of freight was received from the South African railways.

VI. AIR TRANSPORT

(a) *Main Trunk Services*

The British Service. With the post-War development in aviation it was early recognized that air communication between Africa and other countries would be of exceptional value owing to the great distances involved. Much preliminary work was, however, necessary, both in the exploration of suitable routes and in the collection of scientific and other data, before practical steps could be taken for the establishment of air services. In the British territories the exploratory work was done by the Royal Air Force,

and soon after 1919 a beginning was made in the construction of aerodromes along the projected Cape to Cairo route.¹ Flights from London to Capetown were undertaken both by individuals and by companies such as the Blackburn Aviation Company under the initiative of the late Captain T. A. Gladstone, and demonstration flights by Sir Alan Cobham followed; many flyers competed for the record from London to Capetown. It was not, however, till 1931 that a mail service was actually initiated.

In 1923 the government had decided to promote the amalgamation of several air companies into one, Imperial Airways Ltd., for the development of Empire air routes, and in 1930 agreements were concluded between Imperial Airways, the British Government, and the Governments of the Union of South Africa and the other territories concerned, for the institution of a subsidized weekly service of mails and passengers between London and Capetown. In February 1931 the service was established as far as Kisumu² and was extended to Capetown in the following year. The scheduled time for the journey, which at first was eleven days, was reduced in 1934 to ten days and in the following year to nine days. In 1935 South African Airways took over the service south of Johannesburg; in 1937 Imperial Airways discontinued the service to the Rand Airport, and inaugurated the flying-boat service down the East Coast to Durban, the time taken being six and a half days. The Empire Air Mail scheme, which had for its object the carriage by air of all first-class mail without surcharge within the Empire, came into operation in the African territories in the summer of 1937. Imperial Airways has also extended its service in other directions in Africa, and now maintains a branch service from Khartoum to Lagos in Nigeria; the other main stopping places are served by feeder lines which will be considered below.

The French Routes. Two regular air services are now in operation. One, operated by *Air-Afrique*, proceeds, in alternation with the Belgian *Sabena* service, across the Sahara by the eastern route and has branch services to Coquilhatville, Brazzaville, Élisabethville,

¹ H. Burchall, 'Air Services in Africa', *Journal of the Royal African Society*, vol. xxxii, no. 126, 1933, pp. 55-73.

² Sir S. Instone, 'Aviation in Eastern Africa', *Eastern Africa To-day and To-morrow*, 1934, p. 63.

Broken Hill, and Quelimane in Moçambique, and finally to Tananarive in Madagascar; in 1937 the journey from France to Madagascar was scheduled to take eight days. The other, operated by *Air France* with flying boats, covers the west coastal route from Casablanca to St. Louis, where the *Aéro-maritime* service continues to Pointe Noire in French Equatorial Africa. At Dakar there is a connexion with the Paris-South America service, and at Cotonou with *Régie Air-Afrique* and the Belgian *Sabena* line. The *Air France* service, inaugurated in 1937, now reaches French Equatorial Africa in four and a half days. In March 1938 a fast weekly service from Paris to Dakar by *Air France* was begun, scheduled to take twenty hours. It is also announced that a feeder service will connect Dakar with the daily Casablanca-London service. Another branch service from Gao-Gao to Timbuktu was opened in February 1938.

The Belgian Services. The Belgian Government can claim the credit of instituting the first regular air service in Africa. In June 1919 a *Comité d'Études pour la Navigation Aérienne (Senac)* was appointed in order to study the question of the development of air transport in the Belgian Congo and to establish a service between Léopoldville and Stanleyville; the *Sneta (Société Nationale pour l'Étude des Transports Aériens)* undertook this latter work, and the first aeroplane was in commission in 1920. In 1923 a more permanent organization, the *Sabena (Société Anonyme Belge d'Exploitation de la Navigation Aérienne)*, was constituted by the state, the colony, and *Sneta*, with a view to regularizing the services to the Congo and within its area. The *Sabena* now runs a mail service from Europe to the Congo, alternately with the French *Air Afrique*, and the Congo itself is well served with internal communications, most of the important centres in the territory being united by air.

The Portuguese Services. A concession¹ providing for the exclusive development of both national and international airways has been given by the Portuguese Government to the S.P.E.L.A. (*Sociedade Portuguesa de Estudos e Linhas Aéreas*) and the *Companhia Portuguesa de Aviação*; a direct line from Lisbon to Lourenço Marques has been under consideration for some time. In Portuguese East

¹ F. Ribeiro Salgado, *L'empire colonial portugais*, 1931.

Africa, Beira is on the Imperial Airways route; in 1935 Rhodesia and Nyasaland Airways started a weekly service connecting Beira with Nyasaland and Southern Rhodesia. One Portuguese Government line, the D.E.T.A., operates a service from Lourenço Marques to Johannesburg, and other developments are under consideration, in particular for Angola, which at present has no air services.

(b) Feeder or Territorial Services

In the Union of South Africa, including the mandated territory of South-West Africa, matters relating to aviation are controlled by the Minister of Defence, who is advised by a Civil Air Board set up under the Aviation Act, No. 16 of 1923. The Union policy is to ensure that all air services should be state-owned, and in 1934 a state service, the South African Airways, took over the local services formerly operated by a private company, the Union Airways. The Union Government also took over the South-West African Airways in 1935, the Imperial Airways feeder services south of Johannesburg in 1936, and, in co-operation with Rhodesia and Nyasaland Airways, the service from Johannesburg to Lusaka in Northern Rhodesia, extending it in 1937 to Kisumu, the Kenya port on the north-eastern shore of Lake Victoria. The route mileage of South African Airways now aggregates 5,935, and its extension into East Africa appears to have a strategic as well as a commercial aspect. There are thirteen D/F wireless stations in the Union for civil aircraft, and special weather bulletins are issued.

In the High Commission Territories there has been little progress in air transport beyond the provision of landing grounds, of which Bechuanaland has nineteen; the Union service from Johannesburg to Windhoek in South-West Africa crosses the territory. In 1933 Sir Alan Pim drew attention to the value to be attached to the extension of air services.¹

The East African territories have all contributed to the financial arrangements with Imperial Airways in connexion with the London-South Africa route, and have provided the necessary

¹ *Report on the Financial and Economic Position of the Bechuanaland Protectorate, 1933, p. 12.*

facilities in their territories. Air services by companies operating inter-territorially had, however, preceded the main trunk route; and these services now act as feeder lines, maintaining regular communication with the Imperial Airways service. In Northern Rhodesia the Rhodesia and Nyasaland Airways provide a local service to Nyasaland and Southern Rhodesia and also form a link with the service of Imperial Airways. The Wilson Airways began operations in Kenya in 1929 with a regular service linking Nairobi and Dar-es-Salaam. This line has obtained the government mail contract, and has extended its services to the neighbouring territories. In 1936 Kenya maintained customs aerodromes at Kisumu, Nairobi, and Mombasa, and 12 other landing grounds and 19 emergency grounds; in Tanganyika in the same year there were 48 government and 6 private aerodromes and landing grounds. In Uganda development has not been so extensive as in Kenya or Tanganyika; Port Bell is a port of call for the Imperial Airways, but aircraft is little used otherwise in the territory. The customs aerodromes are Jinja, Entebbe, and Port Bell.

In the British West African territories aviation has developed more slowly. It was said in 1935 that in Nigeria there seemed 'to be no demand for air facilities of an elaborate nature'¹ and that the landing grounds were only of an emergency kind. In anticipation, however, of the projected extension of the Imperial Airways South Africa service by a branch line from Khartoum to Lagos, to which reference has been made above, landing grounds were put in order at six centres. The Lagos service started in 1937, and from Lagos it is now continued by Elders Colonial Airways to the Gold Coast and to Freetown in Sierra Leone. In 1936 the Gambia continued a previous agreement with the *Deutsche Lufthansa A.G.* for the carriage of air mail by a weekly service between the Gambia and Europe. There was little or no co-operation with French services on the West Coast until 1937, when these were continued to Accra, thus giving the Gold Coast its first regular air mail. Further developments may be expected, and the preliminary survey of a British air route to the West Coast has been completed by representatives of the Imperial Ministry and British Airways.

¹ *Annual Report on the Social and Economic Progress of the People, 1935*, p. 73.

(c) Finance and Administration

The Union of South Africa is alone among the British territories in Africa in maintaining a state air service on a large scale. In the year 1936-7 the Civil Aviation vote was £52,925 and the subsidy to Imperial Airways amounted to £34,000, a reduction on the previous year, when it was £54,000.¹ It would not appear that any of the aviation companies operating in the other British African territories are self-supporting, and nearly all are assisted by government subsidies, in return for which they contract to carry mail and maintain regular services. Of the subsidy given in 1937 to Imperial Airways by the British Government, £135,247 was in respect of the purely African services.² Of the contribution made to Imperial Airways in 1936 by the African territories, Kenya provided £15,000, Tanganyika and Uganda £10,000, Anglo-Egyptian Sudan £5,000, Southern Rhodesia £10,000, and Northern Rhodesia £2,000.

Among the local services, Wilson Airways is also subsidized, Tanganyika in 1936 contributing £2,000. Rhodesia and Nyasaland Airways receive subsidies from Southern Rhodesia which for 1937 amounted to £1,000. Aviation in the Rhodesias owes much to the Beit Trustees, who in 1932 set aside £50,000 for the improvement of air facilities; a chain of emergency landing grounds on the Cape to London route has been completed from this fund. In 1936 Sir Abe Bailey presented £3,000 towards the development of civil aviation.

The total expenditure of the three Governments of Kenya, Tanganyika, and Uganda on air ground services and aerodromes up to 1937 was respectively £63,900, £19,900, and £8,100, while the total revenue from landing fees and services amounted to £12,000.³ In its estimates for the year 1936-7 the Government of the Gold Coast provided for an expenditure of £75,000 for aerodromes and works; Nigeria provided in the same year £81,445, with a special provision of £19,689 for work in connexion with the extension to that territory of the Empire air mail scheme.

¹ *Memorandum by the Secretary of State for Air to accompany the Air Estimates*, Cmd. 5677, 1938, p. 19.

² *Report of the Committee of Enquiry into Civil Aviation*, Cmd. 5685, 1938, p. 85.

³ Brigadier-General Sir H. O. Mance, *op. cit.*, p. 41.

The Belgian and French companies are also subsidized: in 1936 *Sabena* received 14,428,232 fr. and *Air-France* 154,865,873 fr.¹ The local expenditure is also considerable; the French colonies and the mandated territory of the Cameroons have undertaken an active policy of constructing aerodromes and emergency landing grounds on all the main routes. In French Equatorial Africa the Governor-General announced in 1935 that works costing 1,000,000 fr. would be undertaken and further credits would be necessary. The Belgian Congo in 1936 allocated 1,038,939 fr.² to aviation.

In the British colonial and mandated areas aviation is controlled by the Air Navigation (Colonies, Protectorates and Mandated Territories) Order in Council of December 21, 1937, and the International Air Navigation Convention of 1929 has been widely adopted.

(d) *Général*

It has been seen that at an early stage the Belgian Congo saw the advantage of linking up by air services the more important stations in its widely extended territories, and the French authorities have shown of late years considerable activity in providing air communications in Equatorial Africa, which is poorly provided with other means of transport. The Governor-General of Equatorial Africa has said that 'l'aviation est en train de transformer l'Afrique. . . . Elle a supprimé les énormes distances qui, en Afrique, empêchent toute communication rapide, toute liaison permanente, tout contact régulier.'³ An administration has obviously much to gain from the adoption of a means of transport which will enable its officials to make more frequent visits to areas under their charge; perhaps the most conspicuous example in British territories is afforded by Barotseland, where a few hours' journey in an aeroplane now replaces what at one time was a boat journey of three weeks up the Zambesi. The air services have also proved of use for conveying a special class of goods of high value; they are, for instance, now regularly used for the conveyance of

¹ *Report*, op. cit., Cmd. 5685, 1938, p. 87.

² 240,234 fr. *Budget ordinaire*, and 798,705 fr. *Budgets extraordinaires*.

³ 'Discours du Gouverneur Général de l'Afrique équatoriale française à l'ouverture du Conseil d'Administration, 1936', *Annuaire de documentation coloniale comparée*, 1936, vol. ii, p. 225.

gold from the Kenya, Tanganyika, and Congo goldfields, and diamonds from the Congo and West African mines. There is not as yet, however, sufficient public support to encourage the hope that any considerable extension of the existing services can take place without financial assistance from the administrations; and the financial circumstances of some of the territories are such that even the subsidy now paid constitutes a relatively heavy charge. The speeding up of communications with Europe appeals mainly to one class in the territory; the return for the expenditure is, at this stage, indirect rather than direct. It still remains to be seen if the governments can calculate on a more direct set-off due to the shortening of the period now allowed to their officers for journeys on leave, or to savings effected by concentrating the forces maintained for preserving order, instead of keeping them, as at present, in widely scattered detachments. The question whether administrations can feel themselves justified in assisting to finance the extension of existing services must await the result of further experience; meanwhile it will be necessary for them to undertake the consideration of a number of problems which have already arisen in connexion with the use of the air, such as the international co-ordination of meteorological services,¹ the broadcasting of wireless information regarding weather conditions, and, not least, the possible spread of disease either by passengers or by infection carried in aeroplanes by insects.² A situation is also arising in which it becomes necessary to consider the measures required for closer co-operation between air and rail services in order to eliminate wasteful competition.³

VII. CONCLUSIONS

As the preceding narrative has shown, the policy regulating the development of communications has two different aspects. The first relates to the construction of what may be described as the major lines of communication. At the outset it was natural that administrations should, apart from the need for constructing the simple type of communication required for administrative purposes, attach primary importance to the organization of water and

¹ See E. B. Worthington, *Science in Africa*, chap. iv. ² See Chap. XVII, p. 1128.

³ Brigadier-General Sir H. O. Mance, *Report*, op. cit., p. 41.

rail transport from the seaports to the interior, since, in the absence of any internal market, it was necessary to seek as soon as possible an external market for Africa's actual or potential products. It has often been said that it was Africa's minerals and precious stones which brought her within the orbit of European civilization, by creating the need and assuring the capital for constructing the railroads which unsealed the interior of the continent. This is in great measure true in regard to important parts of Africa, such as the Union, Rhodesia, Moçambique, and the Belgian Congo; it does not, however, apply with the same force to Kenya, Uganda, Nyasaland, Tanganyika, or the larger part of British and French West Africa, where communications were constructed either for the transport of types of agricultural produce which commanded an export sale, or in the general interests of the development of the country.

As a result, the administrations were themselves obliged to undertake the financing of a large part of the expenditure incurred in providing rail and water transport. On p. 1317 of Chapter XIX the estimated capital expenditure on the rail and waterway system of that part of Africa with which this Survey deals has been given as £373,000,000, of which £260,000,000 has been incurred in British and £113,000,000 in foreign areas.¹ The non-state enterprise in the British territories amounts to not much more than £28,000,000; in the foreign areas the amount is less easy to estimate, owing to the complications of the Belgian Congo system of railway finance, but for the present purpose the calculation is not material, since in both the French territories and the Congo the state has either a direct liability for a fixed interest charge or has made itself indirectly responsible for interest through a system of guarantees.² The most conspicuous examples of private, as opposed to state, enterprise are the Rhodesian railway system and the Benguela Railway, but it may be added that the British South Africa Company, which promoted the construction of the Rhodesian Railways and bore the expense of implementing the deficiencies in their debenture interest, acted in this respect as much in its administrative as in its commercial capacity. The financial re-

¹ These figures exclude the expenditure in the Sudan. The capital actually at charge is, as preceding pages have shown, a somewhat smaller sum.

² See above, pp. 1592-4.

sults of both the private and state enterprises are of importance as indicating the possibility of future extensions of the existing rail and water systems. The South African Railways, in spite of circumstances to which allusion will shortly be made, have not only earned the whole of the interest on the capital at charge, but have been able to contribute £54,000,000 to a renewals fund and over £11,000,000 to a betterment fund, which has on occasion been used as a means of meeting new capital expenditure out of revenue.¹ The Moçambique railway system works to a profit² owing largely to its guaranteed share in high-rate Transvaal traffic. Some of the past financial difficulties of the Rhodesian railway system have already been referred to.³ Since their capital was raised mainly on debentures, there is some analogy between the position of the British South Africa Company, which guaranteed the interest, and that of the governments which have incurred fixed interest charges on behalf of their railways; but in the case of the Rhodesias the burden of meeting these charges has fallen on the shareholders of the Company, not on the taxpayers of the two territories.

The Nyasaland railway system, although the capital at charge has been reduced by the assistance given by the Imperial Government, has involved the local administration in what may prove to be an onerous commitment for the payment of interest charges.⁴ The Uganda-Kenya system is self-supporting, though the high rates which it has been necessary to impose on freight have been held to prejudice the general development of the territory, and the situation would be gravely affected if the Imperial Government decided to make a charge on the sum of £5,502,592 which Kenya now enjoys without interest.⁵ Tanganyika Railways took over the German lines free of cost, and a considerable sum advanced by the Imperial Government to meet past deficits is excluded from their accounts; but the experience of the results of the depression period on traffic receipts shows that the system cannot be regarded as self-supporting.⁶ As regards the railway system of the Belgian Congo,⁷ there is little doubt that, with the exception of the *Chemin de Fer du Katanga*, the lines as a whole have not been able to pay

¹ S. H. Frankel, *op. cit.*, 1938, chap. v, p. 381.

⁵ See above, p. 1582.

⁶ See above, p. 1579.

⁷ See above, pp. 1591-4.

interest without state assistance, and that during the depression period the necessity for implementing its guarantees imposed a heavy charge on the state. The manner in which the railways in French West African colonies present their accounts makes it difficult to determine how far they are really self-supporting;¹ the railway in the French Cameroons, a large part of which was taken from the Germans without payment, appears to be able to balance its accounts,² but it is probable that the Brazzaville Railway in Equatorial Africa, of which the cost of construction was exceptionally heavy,³ remains a charge on the revenues of the government. The Benguela Railway has not as yet earned a dividend. In Nigeria the capital at charge is being reduced by the expenditure on that section of the railways which was most noticeably in deficit; the fixed interest charge on the remainder of the system is being reduced, and it is possible that, with this assistance from general revenues, the railways may be able to present in the future a more balanced account.⁴ In view of the heavy deficits in past years, neither the Gold Coast nor the Sierra Leone Railways can be said to be self-supporting.⁵

Approximately half of the 'public listed capital' in British territories has been invested in railways; where, therefore, there has been a deficiency in the railway working, with the result that the general revenues have been obliged to implement the fixed interest on the capital at charge, it has made a serious reduction in the resources available for general expenditure. This has been felt the more because deficiency has often been caused by a depression in commodity prices which has reduced the general revenues without permitting any reduction in the recurring liabilities of the administration. There is nothing unreasonable in the proposition that the general revenues of a territory should bear part of the interest charges involved in the construction of its railway system; the debit arising may with propriety be treated as development expenditure, and the contribution made by the railways to the general advancement of the country may amply justify the state in undertaking this liability. The difficulty in adopting this procedure as a general practice does not lie in any question of principle;

¹ See above, p. 1589.

² See above, p. 1591.

³ See above, p. 1589.

⁴ See above, pp. 1585-6.

⁵ See above, pp. 1586-7.

it lies in the fact that in some territories the resources available make a further commitment of this nature impracticable. That, for instance, was the opinion recorded by Sir S. Armitage-Smith in his review of Tanganyika finances in 1932.¹

It has been suggested that the liabilities incurred by some administrations on their railway account might be reduced if railways were administered on more strictly commercial principles than is now the case. The suggestion raises questions of principle which it is not possible to discuss at length here, but it is of interest to note that the railways of which the policy is held to depart farthest from strictly commercial principles are not, in point of fact, those which are most conspicuous for deficiencies in revenue. Reference has been made elsewhere to the use made of the South African Railways to support agricultural interests in the Union,² and it has been asserted that some £14,000,000 out of the £17,000,000 spent on branch railways has been expended on unpayable lines largely in those interests. The employment of European labour as part of the 'civilized labour' policy has been said to cost the South African Railways £300,000 a year.³ That the railways are nevertheless self-supporting is said by critics of the system to be due to the fact that they have imposed freight charges which press with special severity on the gold-mining industry. Assuming this criticism to be correct, it is clear that there are some points of view from which the procedure might be objectionable; but judged purely as an operation in railway finance, it would not be open to objection unless it could be proved that the freight charges had affected the amount of ore raised or prejudiced the opening of new mines. As already shown, the Act of Union created an organization intended to prevent the use of the railways for the promotion of sectional interests.⁴ It is, however, clear that this object could not be attained merely by the separation of the railway finances from general revenues, nor by the appointment of a Railway Board, unless the constitution of the Board made it entirely independent of the Ministry,⁵ and the railways could obtain capital without recourse to loans from the state.

¹ Sir S. Armitage-Smith, *Report on a Financial Mission to Tanganyika*, Cmd. 4182, 1932.

² S. H. Frankel, *op. cit.*, 1928, paras. 90-1.

³ See Chap. XX, p. 1308.

⁴ See above, p. 570.

⁵ By s. 126 of the Act the commissioners are appointed by the executive government.

The system of financial control devised for the Rhodesian Railways,¹ based on the representation of different territories, appears well calculated to preserve the commercial character of the railways. The Kenya system has been used for purposes similar to those of South Africa, and there is here the added difficulty that the interests of Kenya and Uganda are far from being identical. The machinery of control now in force² does not appear adequate to provide a solution of these problems. In other British territories the criticism which can be levied against the railways is not that their policy is subjected to sectional influences, but that there has often been undue delay in establishing a self-contained railway account, namely one in which assistance given from general revenues to repair deficits will rank as an interest-bearing loan, and a surplus on the annual working will be taken to the renewals fund or the revenue reserve fund of the railway. Until this is done, the management has no incentive to economize in working costs, or to seek for new freight, or to make travelling more attractive to natives.

In the conditions of Africa, the construction of a railway from loan capital often has the effect of creating a mortgage on a marketable production which is not yet visible. There are instances in which a railway has quickly created its own traffic; a typical instance is the extension of groundnut cultivation in Northern Nigeria and in Senegal. In other instances, as for instance in Nyasaland, the increased facilities have been slow to produce a response in the form either of new cultivation or the expansion of existing marketable crops. That there are many areas in which traffic facilities are gravely insufficient is obvious; typical examples may be found in north Nyasaland, Tanganyika, the Northern Territories of the Gold Coast, French Equatorial Africa, and the northern areas of the French Cameroons. But at the moment the majority of the administrations would seem to have decided, in view of their experiences of the depression period, that the extension of railways should be deferred until the character of the probable return has been thoroughly explored. Almost everywhere they have preferred to extend the system of motor roads as an alternative to feeder branch lines. In the course of doing so

¹ See above, p. 1574.

² See above, pp. 1582-3.

they have opened much new country to the cultivation of marketable crops; the expansion of cotton cultivation in the Congo or French Equatorial Africa would, for instance, have been impossible without the motor road as auxiliary to the railway. The experience gained from the use of these roads will enable administrations to determine the economic radius of motor traffic in different conditions, such as cost of petrol (which is subject to wide differences in Africa), the requirements of African or Asiatic producers for traffic, and the like; information thus acquired will provide reliable data for deciding on the practicability of extending the railway system.

As has been shown, the development of motor traffic has in some areas given rise to a number of problems arising from the competition between the motor and rail systems. The competition is felt with special force where import and export rates are widely differentiated. Thus in Kenya exports cannot compete in world markets unless they are carried by the railways at rates which in some cases barely cover the cost of working, and this is made possible by high rates on imports. It is clear that unrestricted competition between transport undertakings is not in the general interest, and some form of regulation of transport must be regarded as essential for co-ordination. If road transport were allowed complete freedom in choice of load, it could undoubtedly undercut the high railway import rates existing in some territories; railways would then lose the revenue necessary to balance low export rates and a situation would arise that would result in heavy deficits, which would have to be made good, in the case of state railways, by the taxpayer. While the procedure used in Kenya of safeguarding the higher-rated railway traffic, by prohibiting the transport of goods, other than local produce, on roads which compete with railways, is held to be effective in present conditions, the expansion of the road system and consequently the existence of circuitous routes and roads alternative to the railways would gradually render it less easy to enforce without injustice to road transport services. One solution of the difficulty that has suggested itself is the creation of a combined monopoly of rail and road services, but this proposal has the great disadvantage that it removes an incentive to continuous improvement in efficiency,

and that it would necessarily affect ancillary road users. A second method suggested for dealing with the problem of competition is that of separate rail and road monopolies with a pooled financial interest; competitive traffic passing by road would pay as toll the amount which the railways would lose, that is, the difference between the railway rate and the out-of-pocket cost of working. The levying of a toll was rejected in Tanganyika owing to practical difficulties of control and to the expense of administration, and subsequent attempts to carry out the principle of a toll, by allowing vehicles to compete with the railway on payment of a high licensing fee, led to loss of revenue without effecting any rational division of traffic. It is interesting to note that elsewhere, notably in Australia, competitive motor vehicles are supertaxed to an extent varying with capacity. In France the proposed taxes on competitive road transport appear in principle to correspond more closely with a theoretical toll. The basis of solution envisaged for East Africa in the recent report of Sir Osborne Mance is protection of the railway monopoly, modified to allow of adaptation to changing conditions, namely, both by modifications in the railway rates and by the licensing of road transport competing with the railways.

The second aspect of transport development to which reference was made above is the need for the provision of communications for the service of purely internal trade. The absence of a developed money economy has, perhaps, tended in the past to obscure the need for facilities of this nature. Occasion has been taken when dealing with problems of Africa's internal economy to refer to the importance which attaches to the development of local markets.¹ The local market is the most potent agency for stimulating agricultural production, and for encouraging the specialization which is essential for the creation of local crafts or industries, as yet hardly existing in many parts of Africa. But over and above this, it is not perhaps generally realized that the larger finance of a country must have its basis in the innumerable petty transactions of small centres of this nature. The construction of the network of roads required for the establishment of local markets is an essential step in building up the economic structure of the **territory**.

¹ See Chap. XX, p. 1421.

CHAPTER XXIV

THE FUTURE OF AFRICAN STUDIES

IN previous chapters attention has been drawn to a number of instances in which there appeared to be need for closer co-ordination in the work of the technical departments operating in different British territories. Thus in regard to the geodetic survey, the compilation of meteorological data, the geological survey, and certain aspects of forestry and soil conservation work, it has been suggested that circumstances seem to call either for the creation of an administrative organization serving more than one territory, or for the institution of conferences or other measures which will secure that joint action is taken by different territories. These suggestions dealt largely with matters falling within the field of departmental administration, and only in a few cases touched on questions relating to research. It is not, however, proposed to pursue here the discussion of the measures required to secure co-ordination of the ordinary activities of the technical departments. The present chapter is limited to the consideration of questions relating to research, whether it be carried out by officers attached to those departments, or by other agencies in the colonies or in Europe.

I. THE SCOPE FOR RESEARCH INTO AFRICAN PROBLEMS

The term 'research' has in practice a wide connotation; it will be convenient here to use it as applying to those specific studies or investigations, in the field both of the social and of the physical sciences, which are undertaken with the purpose of providing a solution to the problems arising in connexion with the material or social development of Africa. These studies may be either of an abstract or (to use a convenient term) of a practical nature; nor indeed can the categories be separated, for it is not possible at any moment to say when an investigation undertaken in the most practical spirit may have to call on the resources of pure science, and it has more than once happened in Africa itself, that a study which appeared entirely theoretical has unexpectedly revealed facts of immediate and very practical use.

That Africa has problems of its own, which require intensive

study, needs perhaps no demonstration. The development of Africa is not a process of gradual evolution; it assumes, as has justly been observed, something of the character of a transformation,¹ and its achievement inevitably demands more than the routine application of existing knowledge. In practically every sphere of work on which this Survey has touched, problems present themselves which require the acquisition of exceptional knowledge, or the application of unusual measures. Thus the task of the health services is not merely to give protection against prevailing diseases; they must seek, in company with the soil chemist, for the factors in the soil which account for malnutrition, and must combine with the entomologist to explore the bionomics of the insect vectors of disease. Often the solution does not even lie in the application of any of the processes of medical science, but in the redistribution of populations in order to avoid contact with sources of infection, or in order to secure for them a better means of nutrition. Again, the objective of the veterinarian may be the cure and prevention of animal disease; but in seeking it, he will have at the same time to concert measures to prevent overstocking with its attendant dangers of devegetation and soil erosion. Even the introduction of mass education has its problem in an unusual diversity of languages, presenting a difficulty that can only be solved by an exceptionally complex study in linguistics. It would be easy to multiply these illustrations; but it may serve the purpose better to give some concrete examples of the special studies which the peculiar problems of Africa would seem to involve.

These examples would include the type of inquiry into social custom and into the effect of contact of African with European civilization which was discussed in Chapter II; the investigation of the linguistic conditions which regulate the choice between the alternative policies of adopting a 'union' language or recognizing a dominant dialect;² and an analysis of the factors necessary for the evolution of a uniform system of law, and a common judicial procedure suited to the requirements of Africa.³ Provision must be made for the examination of the traditional rights in land in different areas, as a guide to the development of a system under

¹ A. M. Carr-Saunders, *World Population*, 1936, p. 306.

² See Chap. III, pp. 81-99.

³ See Chap. VII, pp. 264-6.

which titles can be determined and recorded;¹ and for a study of such part of native social habit as has a bearing on the problems of nutrition, infant mortality, and the incidence of disease.² In the field of the applied sciences, research may be held to comprise studies into the factors of solar radiation which have a share in determining the adaptability of European people to life in tropical areas;³ the collection of bioclimatic data regarding the effect of climate on insect and plant life;⁴ a survey of the character of the water table in areas where well-boring is indicated as an aid to the redistribution of populations;⁵ and an investigation into measures for increasing the supply of fish and meat in order to provide elements which are so often deficient in the normal African diet.⁶

There is a wide field of study presented by the investigation into the factors on which depend the success of different methods advocated for preserving soil fertility in African conditions.⁷ We need, again, a fuller knowledge of the facts of evaporation and of plant transpiration, as a guide to the type of vegetal cover needed for the protection of water sources;⁸ a study of the effect of insect pests on wild animals, of the inter-relation of wild and domestic animals in respect of insect-borne disease, and of the bearing of periodic fluctuations in the wild animal population on diseases such as trypanosomiasis or rinderpest.⁹ It has been urged, again, that we need an extension of the study of systematic botany, and in particular the institution of herbaria, as an aid to research in the problems of agriculture and animal husbandry,¹⁰ or, to take another instance in the same field, the grant of further assistance to local forest staffs in the preparation of check lists and regional forest floras.¹¹ The completion of the arc of the 30th meridian does not perhaps fall under the head of research, but it is a matter not merely of scientific but of practical importance, as providing a basis for the triangulation on which topographical survey must depend.¹² On the economic side, we need, among other inquiries, a com-

prehensive study of the social effects of labour migrations,¹ and a fuller knowledge of the use of marketing systems in the development of native economy.² The list has been selected almost at random; but a study of Dr. E. B. Worthington's *Science in Africa*, published as a supplement to this Survey, will show that it could be widely extended. If it contains few references to the requirements of medical or agricultural research, it is because it appears unnecessary to give illustrations of needs which are at once so obvious and so insistent.

II. OFFICIAL INQUIRIES

It will doubtless have been remarked that the list does not make mention of those types of inquiry which are undertaken by governments in order to provide material for solving their immediate administrative problems. There are typical examples of such inquiries in the appointment of committees to investigate the problem of emigrant labour in Nyasaland,³ or the system of native taxation in Kenya.⁴ There have been some occasions on which inquiries of this character have not been directed to the solution of specific administrative problems, but have had a more detached character, such, for instance, as the studies made by government anthropologists in Nigeria and the Gold Coast, or those regarding native law and custom prepared under the direction of M. Brévié in the colonies of French West Africa.⁵ Inquiries of this nature fall into a somewhat different category from those which are made for the immediate purposes of the administration, and may well be included in that of research.

A wide range of official inquiries is obviously required in view of the novelty of the problems with which the African administrations are continually faced; it is worthy of comment, however, that few territories have an official cadre of a strength which permits them to provide on an adequate scale for the special investigations which they need. It has been of great advantage to India that a definite addition was made to its administrative cadre over and above the strength required by the fixed posts, thus providing a reserve of officers available for special work, including investigations of this type. It may perhaps be added that one of the more

¹ See Chap. XI, pp. 699 ff.

² See Chap. XX, pp. 1421 ff.

³ See Chap. XI, p. 701. ⁴ See Chap. X, p. 572. ⁵ See Chap. II, pp. 47, 50.

urgent tasks of the African colonial governments appears to be the compilation of local gazetteers containing the information required by Administrative and Departmental Officers when taking up a new charge. The District Note Books, of which some description has been given,¹ are far from complying with this requirement, which is of special importance in Africa, in view of the shortness of the official tours of service prevailing in many territories.

The methods followed in the presentation of information also appear to demand greater attention than they have hitherto received. It is not within the French tradition to publish annual reports of the proceedings of their colonial administrations, save in cases where the terms of a mandate make this necessary; the Belgians publish a comprehensive annual report for the Congo, but not reports from the different departments; the British publish annual reports both of administrative and departmental branches of work, and many of these are of great value, but the form in which they are embodied is often unsuitable. As has been pointed out, there is sometimes a failure to discriminate between information which is of public interest and that required solely for departmental use.² The annual reports of the British colonial governments on social and economic progress, and the reports of the British Medical, Agricultural, and Educational Departments follow a standard form, but a more uniform method in presenting reports on many other matters is also to be desired. It is not to be expected that the smaller dependencies should be able to provide the wealth of information which distinguishes the *Year Book* issued by the Statistical Department of the Union; but the British colonies might with advantage revise the selection of the very miscellaneous material collected in their annual Blue Books.

III. THE AGENCIES NOW RESPONSIBLE FOR RESEARCH

Returning to those studies which have been referred to under the general name of research, it is of importance to note the different agencies which are responsible for research in the physical sciences and the sources from which they draw their support. These agencies fall into three categories: international, imperial, and local. The Health Section of the League of Nations has organized

¹ *Ibid.*, p. 49.

² See Chap. XIII, p. 958.

research work of the first class, as, for example, in Uganda in 1926-7 in connexion with the problems of human trypanosomiasis, and now carries on an important study of malaria, tuberculosis, and leprosy.¹ Again, much of the survey work on yellow fever has been done by the International Health Division of the Rockefeller Foundation, which continues to subsidize investigation in Uganda. There is again an international organization for research into problems of locust control; in this case, however, each area carries out its own research, that for Great Britain being in the hands of the Locust Control Committee of the Economic Advisory Council,² which acts through the Imperial Institute of Entomology; other countries have now recognized the latter as the international centre for locust research.³ *The Office International d'Hygiène Publique*, created under the Rome Agreement of 1907, has a number of African delegates. The League of Nations permanent Commission on Biological Standardization has influenced the formation of the Biological Control Laboratory in Capetown for the standardization of vaccines and sera, which has been of considerable assistance to the medical and veterinary services. The International Institute of Agriculture at Rome is concerned rather with the compilation of information than with research.

The development of the imperial research services in Great Britain has a history of some significance in this connexion. Following on the 1851 Exhibition, the Imperial Institute was established in order to act as an institution for consultation, research, and information for the whole of the Empire. The Royal Botanic Gardens at Kew also acted as a centre for the dissemination of information on economic plants and their diseases; one of its most spectacular achievements was the part taken by it in the introduction of the rubber plant into Malaya. The Natural History section of the British Museum also became a centre of information for

¹ *League of Nations International Commission on Human Trypanosomiasis, Interim Report*, 1927; *Final Report*, 1928.

² See below, p. 1618, note 4.

³ The international organization has held conferences in Rome (1931), Paris (1932), London (1934), and Cairo (1936). In Great Britain the Committee of Civil Research started investigation regarding the desert locust; the field of research was extended in 1931 after the Economic Advisory Council took over the work. Field research in the Union is carried out by a special staff maintained by the Union Government; research in the colonies has been carried out under the direction of the Institute of Entomology by a staff maintained by a subvention from the colonies and from the Carnegie Corporation. (See E. B. Worthington, *op. cit.*, chap. x.)

zoological, botanical, and allied studies. But gradually distance, the growing importance of local production for export purposes, or the pressure of the producing interests concerned, led first the dominions and then the non-self-governing dependencies to increase their technical and scientific establishments, and to rely progressively on their own efforts. In part also the impetus came from even more imperative sources;¹ the epidemic of sleeping sickness in Uganda between 1901 and 1905 gave a stimulus to the research in fly-borne diseases; the spread of rinderpest among cattle in South Africa about 1900 led to the appointment of large numbers of veterinary officers by the Union of South Africa and the neighbouring territories; a series of invasions of locusts created an imperative demand for an organization to deal with methods of control.² In the meanwhile, however, a change was taking place in the mother country in regard to the value attached to the organization of scientific inquiry. Interest in the extension of research in the African colonies was strengthened by various influences, among which must be reckoned the position taken up by Mr. Joseph Chamberlain in regard to the study of tropical medicine. The growing feeling on the subject was further stimulated by the experiences of the Great War, and the liberal assistance given by the Empire Marketing Board to research in matters relating to agriculture and animal husbandry, while interest in the study of African social conditions has taken a new direction from the scrutiny to which the mandate system has subjected rival theories of native administration.

It is unnecessary to deal here with the numerous official and non-official organizations for research now existing in Great Britain, save in so far as they contribute also to research on African problems. In the first place, the scientific worker dealing with agricultural and kindred problems in the colonies has the advantage of the information collated and published by the Imperial Agricultural Bureaux established for that purpose in Great Britain. As the result of the Imperial Agricultural Research Conference of 1927, eight bureaux were established at recog-

¹ See Col. S. P. James, *Report on a Visit to Kenya and Uganda to advise on Anti-malarial Measures*, 1929.

² For the history of the creation of the scientific and technical services in the British colonies, see C. J. Jeffries, *The Colonial Empire and its Civil Service*, 1938.

nized centres in Great Britain dealing with different branches of agricultural research.¹ The older established Imperial Institute of Entomology and Imperial Mycological Institute came in 1934 under the control of the joint Executive Council, which since 1928 had regulated the other bureaux.² From these bureaux a large number of reviews, abstract journals, bibliographies, and bulletins containing original papers are regularly published, which serve to keep workers in touch not only with work done in the Empire, but with all other parts of the world. There are also information bureaux attached to institutions for other types of research; there is, for instance, among others, a Bureau of Hygiene and Tropical Diseases.³ In the second place, some of the imperial organizations have taken a part in originating research in Africa. The Economic Advisory Council,⁴ apart from its connexion with locust control, has also committees dealing with tsetse fly, with nutrition, and with dietetics. The first is the organizing centre for tsetse-fly research in East Africa; the last-named committees were responsible for the inquiry into the mineral content of natural pastures, which resulted in the establishment of the station at Naivasha (Kenya) in 1930, and organized the inquiry on nutrition among two of the Kenya tribes which was conducted between 1927 and 1931 by the staff of the Rowett Institute (Aberdeen) in association with officers of the Kenya Medical Service.⁵ In association with the Medical Research Council and the Colonial Office they have lately completed a report on nutrition in the British colonies (1938).

In view of what is said on the subject later, it is of interest to note the position of the three research organizations for which committees of the Privy Council are responsible. They are in-

¹ These include the Imperial Bureaux of Soil Science, Plant Genetics, Animal Nutrition, Animal Genetics, Animal Health, Agricultural Parasitology, Fruit Production. Imperial Bureaux of Forestry and of Dairying are being added as the result of recommendations made by the Commonwealth Scientific Conference of 1936. (*The Times*, July 26, 1938.)

² Imperial Agricultural Bureaux, *7th Report of the Executive Council*, 1935-6.

³ Supported by the Colonial Office. It has since 1931 issued the *Tropical Diseases Bulletin*.

⁴ The Economic Advisory Council reports to the Cabinet and has taken over the functions of the Committee of Civil Research; see Cmd. 3478, January 27, 1930.

⁵ J. R. Orr and J. L. Gilks, *The Physique and Health of two African Tribes*, Medical Research Council, *Studies of Nutrition*, 1931.

dependent but interconnected bodies, with a common chairman in the Lord President of the Council. The Department of Scientific and Industrial Research¹ and the Agricultural Research Council² are not at present directly concerned with research in the African colonies, though they remain in close touch with research institutions in the Union. Some aspects of the work of the former Department, and in particular that of the Food Investigation Board, carried out through the Low Temperature Research Station at Cambridge and the Ditton Laboratory at East Malling, are of particular interest to South Africa. Much of the research may ultimately be of value to other African territories, in particular that relating to the preservation of meat, fish, and fruit. The Medical Research Council³ has a more direct contact with African conditions through its Tropical Research Committee, which includes representatives of the Colonial Office, and of the London and Liverpool Schools of Tropical Medicine. This Committee has created a number of fellowships for tropical research, and has been responsible for investigation into yellow fever, sleeping sickness (Gambia and Tanganyika), yaws (Uganda), and the toxic principle in cassava (Nigeria).⁴ The Experimental Malaria Unit supported by it carries out studies on anti-malarial drugs which have a direct application to Africa. The African colonies will in the future have the assistance of the Colonial Empire Marketing Board created in 1937.⁵

The preceding chapters have given some details regarding the

¹ During the War a committee of the Privy Council was appointed to control the expenditure on scientific and industrial research; an Order in Council of July 28, 1915, created an Advisory Council, which is now in effect the body which manages the Department of Scientific and Industrial Research. Its gross expenditure for 1937 was £890,180. (Cmd. 5647.)

² A committee of the Privy Council was appointed in 1930 to deal with the organization of agricultural research and an Agricultural Research Council was incorporated by Royal Charter in 1931. It found a large number of state research institutions in existence, the votes of the two state departments of agriculture for research and advisory work amounting in 1937 to as much as £388,646, and it has only lately commenced to establish institutions of its own. Its estimates for 1937-8 were £79,510. (Cmd. 5768.)

³ As the result of a provision in the Ministry of Health Act, 1919, the funds provided for medical research are controlled by a committee of the Privy Council through the agency of the Medical Research Council, which was incorporated by Royal Charter in 1930. It should be noted that this is not an advisory body, but controls its own funds; the grant-in-aid for 1936-7 was £195,000. (Cmd. 5671.)

⁴ See Cmd. 5671, 1938, p. 159.

⁵ See Cmd. 5760, 1938, p. 25.

state, academic, or other institutions in Great Britain and the British African territories which are themselves actually engaged in research into African problems; but it may be of advantage briefly to resume that information here, confining the reference, however, to the institutions dealing with social, linguistic, agricultural, medical, and forest matters, and omitting, for the sake of brevity, those concerned specifically with geology, meteorology, zoology, and other studies. It may be said in advance that South Africa can be regarded as practically self-sufficient in the matter of certain types of research. In 1918 a Research Grant Board was appointed to advise the government regarding the encouragement of research in the Union and the administration of government grants in aid of it. A large number of well-equipped institutions have been created for the study of the problems of agriculture and animal husbandry, and the universities are also taking an active part in research of this type.¹

As regards research in the social sciences, most of the non-official field work recently done in British areas, other than the Union, has been directed by the International Institute of African Languages and Cultures,² which has recently also initiated, in association with the Medical Research Council and with the assistance of the Colonial Office, a combined study by a number of anthropological and scientific workers into nutrition conditions in Nyasaland. It is a departure which may have a marked effect on the future course of research in Africa. A scheme for co-operative research in Kenya has lately been undertaken by the Oxford University Social Studies Research Committee. A number of special studies have been supported by grants from the Rhodes Trust. The publications of the Royal Anthropological Institute, the International Institute of African Languages and Cultures, and the Royal African Society are important sources of information on African social studies. The staffs of the South African universities now carry on a number of special studies into native social life in the Union and High Commission Territories, but they no longer receive a subvention from the Union Government for the purpose. The Government of Northern Rhodesia has lately established

¹ *Official Year Book of the Union of South Africa*, 1937, pp. 389 and 956.

² See Chap. II, p. 51.

the Rhodes-Livingstone Memorial Institute, which will be largely devoted to anthropological work, but with this exception the administrations of the British colonies are not at present responsible for any organization of this character. In regard to linguistics, special study in the British colonial areas has, apart from the large body of work undertaken by missionaries, been mainly conducted by the London School of Oriental Studies, and by Fellows of the International Institute of African Languages and Cultures. It may be noted that the work both of the International Institute and the School of Oriental Studies is dependent on terminable grants from the Rockefeller Foundation, as is also the Oxford Social Studies Research Committee; if linguistic study is not adequately supported, students may have to resort to continental centres to pursue their studies. In the Union and Southern Rhodesia much original work in linguistics has been done by the South African universities. The extent to which studies have been instituted by different British administrations into questions connected with African customary law or land systems, has been explained in Chapters VII and XII.

In regard to agriculture, a worker in Africa could look for assistance from the Imperial Agricultural Bureaux already mentioned, from such bodies as the Advisory Council for Plant and Animal Products of the Imperial Institute, or from the Imperial College of Science and Technology;¹ and certain other bodies also take a more or less direct share in research in Africa. Thus the Royal Botanical Gardens at Kew and the British Museum (Natural History) have sent missions to Africa and done much valuable work in the preparation of reference books and the like. The most important of the institutions connected with the study of tropical agriculture, however, is the Imperial Agricultural College at Trinidad;² it is the recognized British centre for post-graduate training on the subject, and its Low Temperature Research Station is the only one situated in the tropics. Reference has been

¹ The college is the head-quarters for the study of insect pests in stored products, and receives subventions from some of the colonies and the Carnegie Corporation for this purpose. It has also been responsible for the examination of fibres and the like.

² Founded on the recommendation of a committee appointed by Lord Milner in 1919 (Cmd. 562); it is supported partly by an imperial grant and partly by subventions from the colonies and from commercial bodies.

made in Chapter XIII to the chain of experimental stations maintained by the Empire Cotton Growing Corporation, which have made a valuable contribution to the expansion in the production of cotton in Africa.¹ Local research on the problems of South African agriculture is well provided for by the large number of institutions established in the Union,² and each of the British colonies and protectorates has one or more of such institutions.³

These are of a varying degree of importance, and specialize for the most part in the problems of immediate urgency arising in their own territories; but there is in the Amani Agricultural Research Station (Tanganyika) an institution intended for agricultural research of a more prolonged and detached character than the staff of a local department could be expected to provide. Amani affords one of the many practical proofs of the emphasis which Germany placed on the necessity for a scientific approach in questions of colonial development. It was founded in 1902, with a scientist of high reputation in charge, and was intended to serve the same purpose as the Buitenzorg Institute of Java, which has had a remarkable influence on tropical agriculture in the Netherlands East Indies. The Amani station fell into desuetude after the War,⁴ but was reconstituted mainly as the result of recommendations made by the East African Commission of 1924, subsequently endorsed by the Lovat Committee on scientific research in the colonies which reported in 1927.⁵ The scale of the establishment is still below that required for a first-class institution.

In regard to the problems of animal husbandry, the Imperial Bureaux mentioned in Chapter XIII⁶ are also available as sources of information and advice to colonial workers. Africa itself possesses at Onderstepoort in the Union one of the most important veterinary laboratories in the world.⁷ Important researches into pasture

¹ See Chap. XIII, p. 945, and E. B. Worthington *op. cit.*, chap. xii. The original endowments of the Corporation came from the profits on the sale of Egyptian cotton during the War by the British Government; its income, approximately £75,000 a year, is derived mainly from a voluntary levy on the cotton imported for the Lancashire spinners.

² See Chap. XIII, p. 945, and E. B. Worthington, *op. cit.*, chap. xi.

³ See Chap. XIII, pp. 947-51, and E. B. Worthington, *op. cit.*, chap. xi.

⁴ It shared in this respect the fate of another important German institution, the Botanic Gardens at Victoria in the Cameroons.

⁵ Cmd. 2387 and Cmd. 2825.

⁶ See p. 944 and E. B. Worthington, *op. cit.*, chap. xiv.

⁷ Besides some endowments, Onderstepoort has an allocation of about £100,000 yearly.

grasses and certain other work affecting animal husbandry are carried out by the Division of Plant Industry at Pretoria and certain of the South African universities. There will be found in Chapter XIII a reference to the various institutions in the colonial territories which carry on the study of the questions affecting animal husbandry.¹

The Imperial Forestry Institute, to which reference has been made in Chapter XIV, is situated at Oxford. Its members have paid several visits to Africa, and the Institute has taken a considerable share in the identification of forest trees and the preparation of check lists.² The Forest Products Research Laboratory at Princes Risborough, maintained by the Department for Scientific and Industrial Research, and the Advisory Committee on Timbers of the Imperial Institute have both given direct assistance in research into forestry problems.

Research into problems connected with health has a wider range. Some mention has already been made of the connexion which different international organizations, and certain British institutions such as the Medical Research Council and the Bureau of Hygiene and Tropical Diseases, have established with medical research work in Africa. It may be added that the Royal Society sent a commission to Uganda to investigate sleeping sickness in 1903 and again in 1910, which resulted in the discovery that the disease was due to a trypanosome. But the British research institutions which remain in most regular contact with medical work in Africa are the London School of Hygiene and Tropical Medicine (with which the Ross Institute is now associated) and the Liverpool School of Tropical Medicine. The former, in addition to conducting in England general work bearing on African medical problems, maintained a mission for inquiry into certain aspects of trypanosomiasis at Gadau in Nigeria, and has also directed a special study in regard to blackwater fever and the helminthic diseases. The latter maintains the Sir Alfred Jones Laboratory at Freetown, which is conducting a survey of diseases prevalent in West Africa. There will be found in Chapter XVII details regarding the institutions for medical research in the Union, where

¹ See p. 947 and E. B. Worthington, *op. cit.*, chap. xiv.

² See E. B. Worthington, *op. cit.*, chap. vii.

the South African Institute for Medical Research at Johannesburg occupies a prominent position, especially in connexion with inquiries into silicosis, tuberculosis, and plague,¹ and also the various institutions in the British dependencies which are connected with research into health problems.² Reference will subsequently be made to the financial support given by Great Britain, through the Colonial Development Fund, to research of different kinds in the African colonies; the undertakings of chief importance to medical science supported by it in recent years are the special research into sleeping sickness and tsetse fly in Tanganyika Territory,³ and a malaria survey at Dar-es-Salaam. The British Empire Leprosy Relief Association has taken some part in the special study of leprosy.

IV. THE CENTRAL DIRECTION OF RESEARCH

The picture thus presented, though impressive in respect of the volume and variety of work in progress, nevertheless reflects the fact that research activities have in the past been frequently undertaken in response to an unrelated series of demands rather than as the outcome of comprehensive planning. Perhaps no area in the world offers more conspicuous proofs than are to be found in Africa of the necessity for recognizing the close interdependence of all scientific effort.⁴ From the ideal standpoint, all the agencies for research into problems arising in the African colonies should be closely co-ordinated, and the human and financial resources available should be apportioned by an authority capable of judging of the relative urgency of the different subjects requiring investigation. But little is to be gained by discussing here the possibility of giving practical effect to such an ideal. Writing on this subject in 1929, the Commission on Closer Union in East Africa regarded it as an accepted policy that scientific work for the Empire would come under central direction, with a chain of interconnected research stations based on central imperial institutions.⁵ The institutions for research in Great Britain have continued to grow in importance, but the policy by which the scientific work for the Empire would come under central direction has been

¹ See E. B. Worthington, *op. cit.*, chap. xv.

² *Ibid.*, chap. xv.

³ See Chap. XVII, p. 1132; E. B. Worthington, *op. cit.*, chap. xvi.

⁴ See, for illustrations of this, E. B. Worthington, *op. cit.*, chap. i.

⁵ *Report of the Commission on Closer Union of the Dependencies in Eastern and Central Africa*, Cmd. 3234, 1929, p. 133.

replaced by one of collaboration through the means of information supplied by the Imperial Bureaux, the assembling of Imperial Conferences, and the action of the Imperial Economic Committee.

So far as concerns the progress of scientific or other research in the African colonies, the study made in the course of this Survey suggests the following considerations. In the first place, whatever may be the position in regard to research organized by the universities or by scientific bodies, that which is undertaken for purposes such as those now under discussion may reasonably be regarded as 'commissioned', in the sense that the authority on whose behalf it is undertaken may properly indicate that one subject of inquiry should occupy attention in preference to others. But the co-ordination of research, in so far as it involves the indication of methods to be followed, or the apportionment of responsibility among different workers, must be entrusted to scientists, and more especially to those who have a position of prestige or authority in the particular subject which is to come under inquiry. The co-ordination of research cannot, in effect, connote the regulation of a large number of branches of investigation by one central executive authority; it implies only the process of devising, in association with the appropriate scientific authorities, the measures for making the most profitable use of the agencies concerned with any one particular branch of study, be it anthropology, medicine, or agriculture, and for maintaining the necessary contact between them and the agencies concerned with kindred branches of work.

It may at this point be of some advantage to summarize the procedure which has so far been followed in the attempts made to co-ordinate the work of research in African problems. We must take account in the first place of the influence exerted by the activities of special organizations, such as the Medical Research Council, the Tsetse Fly, Locust, Nutrition, and Dietetic Committees of the Economic Advisory Council, or the Health Section of the League of Nations. There is, in the second place, the influence of conferences which have been held, both in Great Britain and Africa itself, dealing with a variety of special interests. Of the former, reference has already been made to the Imperial Agricultural Research Conference of 1927; of others there may be mentioned the Imperial Botanic Conference of 1924, and the Commonwealth

Scientific Conference of 1936. There have been frequent conferences of the Survey Officers of the Empire, and there have been four Empire Forestry Conferences, of which one of considerable importance to the African colonies was held in South Africa in 1935. The most recent of the Empire Conferences (1938) has dealt with soil conservation, nutrition, and veterinary work.

Among conferences held in Africa, importance attaches to the meeting of the British Association for the Advancement of Science held at Capetown and Johannesburg in 1929, which aroused unusual interest in certain characteristic aspects of Africa, notably the mineral deficiencies of the soils and their effect on the problem of deficiency diseases. South Africa now has its own Royal Society and an Association for the Advancement of Science. The International Geological Conference met in South Africa in 1929. There was a conference of the representatives of the Health Services of African territories and British India at Capetown in 1932, and a Pan-African Health Conference met at Johannesburg in 1935, both held under the auspices of the Health Section of the League of Nations. There have also been a number of local conferences. In East Africa there have been regular meetings of heads of technical departments in connexion with the periodic Governors' Conferences, and a special interest attaches to those which have been convened to consider the question of the co-ordination of research, such as that held at Amani in 1931 to discuss the general reorganization of agricultural research, and those at Entebbe in 1933 and Nairobi in 1936 to discuss the co-ordination of medical research.¹

In the third place, account must be taken of the effect of the organization created in the British Colonial Office in order to assist the Secretary of State in his general direction of the policy

¹ As examples of other conferences may be mentioned that on research into trypanosomiasis (Entebbe, 1923); on soil chemistry (Amani, 1932, and Zanzibar, 1934); on research into tsetse and trypanosomiasis (Entebbe, 1934 and 1936); on the co-ordination of agricultural research and plant protection (1934 and 1936); on the co-ordination of veterinary research (1934); on the future of agricultural research (Amani, 1936); and on rinderpest (Nairobi, 1938), the last being attended by representatives of the Union and nine other territories. The West African conferences have been fewer in number, but there may be mentioned the meeting of West African Agricultural Officers at Ibadan (1927) and in the Gold Coast (1929); of soil chemists in 1930; and a Veterinary Conference at Vom, in Nigeria, in 1932, attended also by French representatives. A conference on yellow fever held at Dakar in French West Africa was attended by representatives from the British West African colonies.

of the technical and scientific departments in the colonies and protectorates. Mention has already been made of the fact that the Secretary of State now has the assistance of a number of Advisory Committees, and of his specialist Advisers.¹ The Advisory Medical Committee dates originally from 1909, the Advisory Committee on Education from 1923, the Advisory Council on Agriculture and Animal Health was instituted as the outcome of the report of the Lovat Committee of 1927, to which reference has already been made. The Colonial Forest Resources Development Department was created in 1936.² In the course of the chapters dealing with agriculture, health, forestry, and erosion some information has been given as to the extent to which the Colonial Office, with the aid of its Advisory Committees, can be considered as having been effective in the co-ordination of the work of the colonial scientific and technical departments. There can be no doubt as to the great value of the contribution which these committees have made to decisions on policy, but such practical measures of co-ordination as have been effected are perhaps due mainly to the influence of the Secretary of State's Advisers in the course of their tours in Africa.

All credit must be given for the achievements of the workers in the colonies, the more so as some of them were not expressly recruited for research work; it would be possible to quote many instances in which original studies made by them have had immediate results of great practical value. But the impression remains of a lack of direction in certain branches of work, and some duplication of effort;³ and it is noticeable that the Standing Medical Research Committee of East African territories has recommended the appointment of a Director of Medical Research for East Africa, in order to secure better use of the resources available.⁴ The East African Governors' Conference of 1937 had before it a similar proposal in regard to veterinary research. The influence exerted in the direction of co-ordination by the operations of

¹ The post of Legal Adviser goes back to 1867. That of Secretary to the Advisory Committee on Education was created in 1923, and a Joint Secretary was added in 1928; a Financial and Economic Adviser was appointed in 1925, and a Chief Medical Adviser in 1926, an Agricultural Adviser in 1929, a Forest Economist in 1936, and an Adviser on Labour in 1938.

² Some of the Advisers are not technically a part of the Colonial Office, a share of their salary being found from subventions from the colonies and other sources.

³ See *Report*, op. cit., Cmd. 3234, 1929, p. 133. ⁴ See Chap. XVII, pp. 1203-4.

the Colonial Development Fund is inconsiderable. In the first place, the Colonial Development Advisory Committee¹ takes account only of schemes which have initiated in the colonial administrations and have their support; in the second, the proportion of the resources of the fund which have been devoted to research was until recently of minor importance. From 1929, when the fund was established, up to 1938 the sums recommended for all colonies, including both loans and grants, totalled £7,284,682, of which £448,261 was classified as expended on scientific research; the average expenditure on the African colonies appears to form about 55 per cent. of the total expenditure from the fund.

In any attempt to ensure the better organization of work of this nature, great importance attaches to the possibility of securing that the research institutions of Great Britain should take a larger share in African research, as an alternative to the expansion of the establishments employed in the colonies. It will be remembered that under the system adopted in the French, and to some extent in the Belgian, territories research in colonial problems is carried out mainly through the agency of the metropolitan institutions, which dispatch 'missions' to Africa for the purpose, and where necessary utilize the services of the local staff as field workers.² It is possible that under such a system full regard may not always be paid to local needs, and the local staff may tend to lose some of its sense of initiative, but the procedure has at the same time certain advantages. A metropolitan research institution is more likely than is a colonial service to attract the services of men who have decided to make their career in research; they are detached from the responsibilities of purely routine work; and so long as they serve a central institution they share in that scientific atmosphere, at once critical and stimulating, which can so seldom be found in a colony. In a study which is of great value in considering the organization of colonial research, Sir John Russell³ has pointed out that 'there is no advantage in attempting to fuse scientific discovery with scientific exploitation'. If the metropolitan organiza-

¹ The Committee is a body nominated by, but independent of, the Colonial Office and makes recommendations direct to the Treasury for grants or loans to colonial administrations. See Chap. XX, p. 1321, for a further analysis of expenditure from the fund.

² See Chap. XVII, pp. 1171 ff.; E. B. Worthington, *op. cit.*, chap. xv.

³ *Report on the Work of the Imperial Council of Agricultural Research in India, 1937*, p. 4.

tions were to take a larger share in carrying out research, there would still remain for the specialist services in the colonies a wide field of scientific activity in dealing with the many immediate problems which arise in their department of work. In principle, therefore, there is much to be said for a system which would make a more extended use in Africa of the agency of the imperial research institutions.

In a matter which presents such obvious difficulties, concrete suggestions can be put forward only with some hesitation. There are two issues involved, first the furtherance of research in African problems, and second the provision of some effective means for making knowledge of Africa more accessible not only to the public but to those interested in the special study of African questions. As for the first point, it is hoped that there will be no difficulty in accepting the strength of the case put forward in this Survey for the extension of the existing facilities for research into African problems. We have now provided the framework on which social advance must be built up; in many areas we have made a substantial beginning in organizing the social services and in creating the institutions which will supply a training in local self-government. History will doubtless look back on this period as being the most critical stage of African development; errors that are made now for lack of the knowledge which a well-considered scheme of special study might supply may well create situations which the future can rectify only at the cost of great effort and much human distress. It has been well observed that in the undeveloped state of the greater part of Africa, the wide field which is offered for systematic inquiry promises rich rewards to those investigators whose measure of success is the consciousness of having made a further contribution to man's control of his environment; but it is equally true that every year which passes threatens to rob their effort of its value, since conditions are likely to develop which may make it progressively more difficult to apply the results of investigation and experiment.

V. THE CREATION OF A SPECIAL FUND FOR RESEARCH

It is not, however, feasible for the African colonies to make provision for research on the scale required, unless they receive liberal assistance from the British Treasury. There are, in the first place,

some territories which are so far from being able to finance further research that they can at present make little progress with the organization of their essential services.¹ In the second place, many of the problems which require investigation are not confined to one territory or even group of territories. Administrations which are already embarrassed to meet the many insistent demands on their finances may well be inclined to wait on the chance that their neighbours may originate inquiry, or, if they are asked to combine with others, may find that the resources available for work of this nature are already engaged, owing to pressure of some local need. It is, again, necessary to reckon with the tradition bred of hard experience in the development of African territories; it has been a constant struggle to provide their people, who are of low taxable capacity,² with the most rudimentary of the services which their introduction to civilization demands. It is inevitable that the many immediate necessities of the administrations should take precedence of provision for inquiry and research.

There are, however, certain facts which seem to justify an appeal to the British Treasury. At an earlier stage of colonial history, financial relations with the colonies were regulated by a policy which held that they should receive assistance from the Imperial Treasury only in exceptional circumstances, such as those created by military operations or the like. The analysis which has been made in Chapter XX of relations with the colonies in recent years shows that this policy no longer holds the field; the passing of the Colonial Development Act of 1929 gave statutory recognition to the obligation to assist the colonies at this period of their development. It should not be forgotten, again, that Great Britain when establishing the Empire Marketing Board in 1926 voted grants-in-aid of £1,000,000 annually, out of which large sums were expended on research into colonial problems of many different types. The provision which parliament made for scientific and industrial research in Great Britain, when the Privy Council Committees were first constituted in 1918, was an initial sum of £1,000,000, and the annual expenditure on the research conducted under their auspices now exceeds that sum.

¹ See analysis of the present financial position, Chap. XX, pp. 1432 ff.

² See the figures given in Chap. XX, p. 1433.

If an adequate provision could be secured for research in Africa, preferably in the form of an annual non-lapsing grant-in-aid, it is suggested that the most suitable body to administer it would be either a committee of the Privy Council or the Economic Advisory Council of the Cabinet. The different organizations for scientific inquiry for which these bodies are now responsible are in close touch with research institutions in Great Britain, and experience has shown that they have found no difficulty in working in the fullest collaboration with the Colonial Office or with executive authorities. It is possible that they would be able to establish easier relations with the Union or with foreign governments than would a body designed to deal solely with colonial matters. Again, no one can fail to be struck by the small part which the British universities have taken in the special study of matters concerning the colonies; a managing body such as that now suggested would be well suited to attract the necessary assistance from them. It is, finally, only an authority of this character which can move effectively in regard to certain classes of inquiry which do not attract the interest of any one administration in particular; the investigation into problems of nutrition has, for example, been due to the Economic Advisory Council, and there are other matters which seem to await the support of some similar body.

It is assumed that the body administering the fund would not institute research directly, but would operate through existing institutions in Great Britain already engaged in anthropological, linguistic, social, or scientific research, or through the medium of grants to colonial governments, after obtaining in the latter case the assent of the Secretary of State, who would necessarily be represented on the managing body. It may also be suggested that the managing authority would gain greatly by the periodic appointment of two travelling commissioners, representing respectively the scientific and social interests in research; their combined observations would assist it to judge the relative merits of different schemes presented to it.

Various schemes have from time to time been put forward for the closer co-ordination of local research activities in the African territories. A typical scheme of this nature is that considered by the Conference of East African Governors in 1937 for the co-ordination

of medical research. If, however, the suggestions which have just been made for the furtherance of research in colonial problems were accepted, there would be a certain range of inquiry which would in any case be largely undertaken by missions from the home institutions. For the rest, a distinction must be drawn between types of investigation which can profitably be centralized, of which the study of human and animal diseases is the best example, and those, such as agriculture and the stock-breeding side of animal husbandry, which can best be pursued in a variety of local institutions designed to take account of the diversity of soils and climate. In respect of medical research there is much to be said for the institution of an organization serving a group of territories, and supported by a self-contained fund, constituted by annual non-lapsing subventions from the group of colonies concerned. It is to be assumed that the amounts would be fixed for a term of years by legislative enactments, and the fund managed by a representative committee which would choose its own president. Research officers would either be obtained by the committee on deputation from the Colonial Medical Service, or engaged on contract for a term of years. This scheme would secure for local medical research the necessary continuity of resources and independence from routine work. Management by a committee which gave its president the necessary executive powers would possibly be more successful in the circumstances than the proposed appointment of a Director of Research. Such a scheme is equally applicable to veterinary research; it was indeed proposed at one time to centralize all veterinary research for East Africa at Kabete in Kenya.¹

It is very doubtful, however, if a scheme of this nature could be applied to agricultural research, or to experiments in stock breeding or similar activities connected with animal husbandry. In these spheres of investigation the work of the research student must constantly be checked by practical application, and there is always a danger that laboratory study may outrun the possibilities of use in the field; it would seem that, in India at all events, the stage has been reached at which the machinery for gaining more knowledge is working better than the machinery for utilizing it.²

¹ *Report*, op. cit., Cmd. 3234, 1929, p. 134.

² Sir John Russell, op. cit., pp. 3-6.

As already stated, some measure of co-ordination in agricultural investigation is already ensured by the visits of the Agricultural Adviser of the Secretary of State; for the rest, both here and in some other fields of work, the best solution is probably to be found in the systematic application of the procedure of local conferences.

Considerable importance attaches to the extent to which a Provincial Commissioner or similar administrative authority is placed in a position to co-ordinate the work of local departmental officers. Some of the general aspects of the subject have been discussed in Chapter VI; it must here be emphasized that the exercise of co-ordination must in this case be understood as implying only the formal power to require Departmental and Administrative Officers to meet in periodical conference, with an obligation to refer to competent authority the points on which agreement cannot be reached locally. The British system does not contemplate the more complete subordination of the departmental to the local administrative authorities which is usual under the French system.

VI. THE INSTITUTION OF A BUREAU OF INFORMATION

The second issue, to which reference was made on p. 1629, concerns the provision of means for making information concerning Africa more readily available. It has been seen that there are a number of journals which are devoted exclusively to social, linguistic, and similar studies of Africa, such as *Africa*, the *Journal of the Royal African Society*, or *Congo*; there are, in addition, certain journals published locally in the African colonies.¹ The publications issued from Brussels by the *Institut Colonial International* are a valuable source for the documentation of the legislative and similar proceedings of colonial governments,² and its periodical sessions have produced a useful series of discussions on different problems in administration. The bulletins of the Imperial Agricultural Bureaux and the journals and reports published by the medical and other research institutions in Great Britain contain full information of the progress of scientific investigation, though they do not as a rule distinguish the matters which particularly concern Africa. There is in addition a growing mass of general literature

¹ For details see Chap. II, p. 59.

² See in particular the *Annuaire de documentation coloniale comparée*, issued yearly.

on Africa; the formative period of Africa's history, unlike that of India, falls in an era when there is a wide public interest in the comparative study of human institutions. But these sources of information are very scattered; in some cases, as for instance in certain of the French and Portuguese territories, they are difficult of access, and in general there is a difficulty, to which the authors of this report can certainly bear testimony, in readily obtaining all the information required by those who take an interest in the economic or scientific aspects of African development.

We note in this connexion that the International Institute of African Languages and Cultures, though primarily engaged in promoting social and linguistic studies, has, through its affiliations in other countries, many advantages in obtaining information, especially on the subjects with which it mainly deals. On this ground, therefore, as well as on that of its value in organizing research, we hope that it may secure the support needed to enable it to continue and extend its work.

In the absence, however, of any agency qualified to fulfil all the purposes we have in view, we strongly advise the institution of an African Bureau, preferably situated in London, and designed on lines which would make it not only a source of information on practically every aspect of activity in Africa, but a convenient body to maintain close contact with institutions and voluntary organizations in this and other countries interested in African development. It should again be so constituted as to be capable of providing guidance to those who seek to pursue a special study in any subject of interest in Africa, or of placing them in touch with those who are competent to do so.

As outlined by us, the scheme contemplates the appointment, either honorary or part-time, of a director who should himself have some experience of the requirements of social or scientific investigation. He would have as assistants three specialists, acquainted with African conditions, and with knowledge respectively of scientific, economic, and social (including administrative) subjects. They would publish periodically a survey of contributions made to the knowledge of Africa, and of events which affect workers in any branch of study. Their own contribution, it is true, would not be the result of any original study; they would be deal-

ing with information, much of which would be recorded in some form or another elsewhere. But the Bureau would be a clearing-house of knowledge, and would carry the additional advantage that its staff would be capable of indicating sources of information which inquirers could otherwise obtain, if at all, only by a prolonged search, or as the result of a good deal of circumlocution. If it develops in the manner foreseen by us, the Bureau would form a common meeting-ground where personal contact could be established between those who desired to improve their knowledge of African affairs, and it might in time become the natural centre for discussion or conference between non-official bodies.

We have not ventured to put forward a figure for the cost of the major proposal recommended by us. Any estimate of the amount which should be considered appropriate must depend on the value which is, in the opinion of the British Government, to be attached to research in relation to the other forms of assistance which they can render to the colonies. It is of course obvious that of any sum available for this purpose a considerable part must in any case be devoted to purely material services or to the application of scientific processes whose operation requires no further investigation. Communications must be constructed, water supplies improved, educational institutions assisted, the accepted routine of medical, agricultural, and veterinary work must be extended. But there will nevertheless remain a large field in which provision is required for research; indeed, liberality in regard to some types of development expenditure may prove to be misplaced, in the absence of the special knowledge which research alone can provide.

In regard to our proposal for an African Bureau, we estimate the initial expenditure at about £10,000 a year, including the renting of suitable accommodation; this expenditure would doubtless increase if its work developed in the direction indicated by us. While we hope that this institution would receive full support from the British Government, we should prefer to see it controlled by a non-official body, which would be in a position to seek assistance also from colonial governments and from other sources.

CHAPTER XXV

SUMMARY AND CONCLUSIONS

I. THE PHYSICAL BACKGROUND

AFRICA's most important physical characteristic lies in the fact that it has a larger proportion of tropical area than any of the continents; from the human aspect its most striking feature is the fact that, with the exception of Australia, it has the lowest density of population in relation to its area. The first of these facts has a special significance in relation to the possible extension of European settlement in Africa. The land lying 3,000 feet above sea level is contained in a block which embraces the greater part of South and South-West Africa, and runs north-east as far as Abyssinia. But it must remain open to question, until further knowledge has been gained, whether the more tropical portions of the 3,000-foot plateau are suited for the permanent residence of a European population. It would certainly add to the knowledge necessary to form a judgment on this question were scientific studies undertaken of the effect of solar radiation and of equatorial climatic conditions on the health of Europeans; so far little has been done in this direction.

The low population density would seem to be connected in some measure with the existence of known deficiencies in the constitution of the soil, and with the prevalence of diseases facilitated by the malnutrition associated with such deficiencies. This fact gives special importance to the necessity for a scientific approach by the African governments to the interrelated problems of agriculture, animal husbandry, and health.

As regards our knowledge of the surface of Africa, a great number of areas still await a topographical survey sufficient to provide the mapping needed for the handling of social problems as well as for the work of material development. But it is first necessary to supply an adequate geodetic framework on which a successful topographical survey must rest; a correctly established system of triangulation is equally necessary for the cadastral survey of property, mineral rights, and the like. The arc of the 30th meridian,

begun at the Cape early in the century on the advice of Sir David Gill, has not yet been completed.

The extension of air communications to Africa has created an urgent need for the intensification and, above all, for the co-ordination of meteorological work.

II. THE AFRICAN PEOPLES

While there is no reason to question the correctness of the accepted derivation of the African peoples from three principal stocks, Bushmen, Negro, and Hamites, there has been no such anthropological survey as would enable a classification of tribes to be made on the basis of physical characters. The classification of tribes now in use follows for the most part differences in language and culture traits. For present purposes, however, a study of racial origins is of less importance than that of the reaction of African cultures to the influence of European civilization. The social anthropologist can fulfil a practical function by providing material which will enable the African governments, in directing their own policy, to see that the process of adjustment to new conditions shall cause as little disturbance as possible to African society.

The British administrations do not now give any direct support to the study of African social institutions by trained non-official workers; they might, however, find it to their advantage to utilize the services of anthropologists on prescribed lines of special study, working in association with their own officers.

Anthropological study has a further relevance in so far as observations made on African social life may be able to throw light on the existence of a characteristic African mentality. The view taken in this Survey is that the social conceptions and practices of Africans are the result of a natural process of accommodation to their economic and physical environment; there are few customs for which a parallel could not be found, either in the past or the present, among peoples similarly circumstanced. Their social conceptions do not therefore necessarily indicate any intrinsic difference of character or mental capacity between them and other peoples. Of recent years attempts have been made to find in the examination of the brains of Africans a basis for conclusions on their mental capacity.

It does not, however, appear possible to base on inquiries of this nature, or on the application of 'intelligence tests', any conclusion which will assist in the determination of general administrative policy.

III. THE STUDY OF AFRICAN LANGUAGES

It is customary to reckon the languages of Africa as 700 in number. Their diversity constitutes a problem of special difficulty when (as in the majority of British territories and the Belgian Congo) policy has determined that popular education shall be given through the medium of the vernacular. It is in such cases necessary to decide whether the language chosen shall be a dominant vernacular, or a lingua franca (like Swahili in East Africa), or a composite or 'union' language, such as is employed in parts of West Africa. The decision on this point is of importance in connexion with the encouragement given by the state to the production of text-books and the growth of a vernacular literature. A second problem lies in the need for finding a standard orthography to take the place of the variety of symbols used by those who first reduced the African languages to writing. For the solution of these problems an administration needs the assistance both of experts in linguistics and of those who can advise it as to the social consequences likely to follow any course recommended to it.

It is in Africa of special importance for the student to follow modern methods of study, including attention to the analysis of speech-sounds. While the standard of linguistic proficiency attained by some government officers is high, the British Government has hitherto given less support to institutions devoted to the study of African languages than, for instance, has the German Government, and it may further be questioned whether either the African governments or commercial firms attach sufficient importance to the attainment of linguistic efficiency by their servants.

IV. POPULATION RECORDS

In the last hundred years the estimates of the population of Africa have been as low as 28,000,000 and as high as 205,000,000; expert authority now limits itself to the view that the present total may lie between 138,100,000 and 163,300,000, a fact which affords

an indication of the value which scientific opinion attaches to the systems of enumeration now in use. In the present state of our knowledge, it is only possible to say that the African population is probably now either stationary, or subject to a very slow increase.

In recent years an increasing interest has been shown in census enumerations. In many cases, however, calculations, based on the number of male taxpayers or the like, still take the place of enumeration; it is indeed possible that greater accuracy will not be attained until Africa is able to call upon the services of a much larger number of literate enumerators. The conclusion is unfortunate, since more accurate vital statistics are essential in determining policy in such matters as the regulation of labour recruitment, or planning for education and health organization. Nor is it at present possible to check the correctness of many current assumptions, such as those relating to the extent of infantile mortality, or the effect on the birth-rate of African marriage customs.

It is suggested that administrations might, as a first step towards the improvement of their vital statistics, introduce a system of registration of births and deaths in all areas in which means can be found for ensuring a reasonable accuracy in registration.

V. POLITICAL AND SOCIAL OBJECTIVES

The presence of a considerable European element in some of the British territories has given to discussions on the political future of the British colonies a more concrete form than that taken by discussion regarding the French or Belgian possessions. The political future which British policy has assigned to the African colonies must be understood to be that of self-government based on representative institutions. The pursuance of this policy has involved the devolution of as large a share of authority as possible to the executive government of the colony and the recognition of local legislation as the source of law. Administrative policy generally gives the impression of being initiated by the local unit rather than directed from the centre. It is important to note the operation of these principles in regard to the development of a policy or native administration. In both West and East Africa the prevailing policy is now that of indirect rule. In West Africa there has been no European colonizing interest, and consequently less direct

impetus towards the development of responsible self-government than in East Africa; but the principles of indirect rule, if not incompatible with the ideal of self-government by representative institutions, are at all events so far alien to it as to suggest that native institutions must be materially modified if they are to fit into any scheme involving an elected parliament. In East Africa there is also a difficulty of another type: in areas such as Kenya or Northern Rhodesia, responsible self-government would normally involve either an arbitrarily arranged predominance of the European minority, or the political supremacy of the native majority. This is the problem which lies at the back of the many attempts, beginning with the White Paper of 1923, to find a formula which will enable Great Britain to maintain the ideal of responsible self-government, while at the same time remaining loyal to its obligations as trustee for native interests.

The objective of South Africa and Southern Rhodesia involves no such logical difficulties. Their aim is the preservation of the social and economic standards of European civilization, and in South Africa the supremacy of the European in these fields has its corollary in the political field, where the representation lately conceded to natives provides access to a consultative body, the Natives Representative Council, and not to the South African Parliament.

French policy does not envisage a future of self-government for her colonies; development is, in their case, regarded as fitting the colony to occupy in reality the position now assigned to it in principle as an integral part of France. The emphasis is, therefore, not on their securing a growing measure of political rights, but on their progressive access to French culture and legal institutions. The older colonial system, which foresaw a wide admission of native 'subjects' to French citizenship and a share in electing representatives to the French Parliament, has given place to one in which the access to French citizenship is greatly restricted, and the representation given to the great majority of Africans is confined to membership of consultative bodies. Former tradition still asserts itself, however, in the retention of a centralized system of administration, in which the main source of legislation is the ministerial decree, and in which executive devolution is a concession to the influence of personality rather than to principle.

Belgian colonial policy also avoids any conception of the Congo as a self-governing entity; on the other hand, it shows no tendency to regard it as a Belgium *outremer*. But policy only began to take shape after the Great War, and there are still many points on which it has not fully declared itself. The state has a direct interest as a shareholder in a large number of Congo enterprises and has paid great attention to the material development of the colony. The policy of material development is, however, combined with a conscientious recognition of the need for safeguarding the conditions of labour, promoting health organization, and improving the means of subsistence.

The objective of the Portuguese rule can be characterized more clearly when the reorganization introduced by the Colonial Act of August 1935 has come more fully into effect. The present government inherited an empire burdened with an unenviable tradition of mismanagement. The reconstruction carried out by Dr. Salazar's ministry is directed in the first place to securing financial stability; in political matters it is apparently intended to introduce gradually, and with modifications required by the state of native development, the corporative methods of the New State of Portugal. Loan funds have recently been secured to further the colonization of Angola, the Cinderella of the colonies.

VI. SYSTEMS OF GOVERNMENT

In South Africa the policy just outlined has resulted in recent years in the passing of a comprehensive series of measures intended to implement the principle of racial segregation. There has at the same time been an increasing recognition of the need to assist the native to develop himself within the separate but subordinate field which current policy assigns to him. In the British colonies the most important problem of a political nature which now faces the British Government is the question whether to give increased representation to Africans in the legislative councils and to concede the system of an elected majority; it must be realized that these measures might create a commitment to the grant, at some future date, of responsible self-government. The French system, as shown above, has in comparison a more clearly defined political objective. For the present there seems to be little in the

nature of political movement in the French African colonies; but only experience will show whether the more flexible character of the British system will not enable its institutions to adapt themselves more readily than those of the French colonies to the political situations which the future seems certain to entail.

An examination of the working of the mandatory system suggests that it is unlikely that it will result in establishing uniformity in methods of administration; its chief value lies not in its control of specific administrative policies, but in the publicity to which it subjects the mandatory governments.

Among the different proposals that have come under discussion for the regrouping of British administrative units, the most difficult is that connected with the scheme for federation in East Africa. It is clear that some greater co-ordination in administration is desirable. The obstacle lies less in the existence of a strong settler interest in Kenya, since allowance could doubtless be made for this in a suitably devised form of federation, than in the objection felt to bringing Tanganyika, as a mandated territory, into a federation of British possessions.

In the field of administration a difficult problem arises in regard to the co-ordination of the relations between the technical and administrative services. The development of Africa now depends on a progressive activity of the scientific and technical branches. The problem of co-ordination offers no great difficulty under the French system, but in the British colonies, where native administrations are taking a growing share in local government work, some method has still to be found which will place the Administrative Officer in a position to represent the interest of the native administrations without prejudicing the independence of the departments in technical matters. Some importance attaches to the suggestion that the technical departments should be suitably grouped under secretaries to the government.

The lack of continuity of administrative personnel, due to the constant transfer of officials, is a feature common to all African administrations; this problem has so far found no suitable solution.

As compared with other administrations, British officers appear to be unduly occupied with routine work. Both in administrative and technical branches the expansion of activity can only be

secured by the employment of educated Africans. France assigns a definite place to this class in her official cadres, and her educational system is specifically designed in order to produce it; but though a considerable number of Africans are employed in places of independent responsibility in British West Africa, the government has failed to issue any general statement of policy as to the extent or manner of their employment in the African dependencies.

VII. LAW AND JUSTICE

Native Africa had its own systems of customary law and of justice, chiefly designed to maintain the social equilibrium of the different societies of which Africa is composed. It is to be regretted that students of jurisprudence have paid little attention to the problems arising out of the introduction into Africa of a modern system of law, the chief purpose of which is to regulate behaviour in accordance with European concepts.

The most effective sanction which any system of law can command lies in evoking some measure of agreement from those to whom it is applied. This is, indeed, the chief problem for the lawgiver in Africa to-day. For the most part the governments, other than that of the Union at an earlier stage of its history, have interfered as little as possible with the African customary law regulating matrimonial relations, succession, and the like. In the second place, they have made an increasing use of the native court as an agency for trying most of the civil issues arising between natives, and all but the most serious criminal issues. The essential feature of the native court is that it tries issues by native law and retains its own customary procedure, a fact which accounts for its popularity over the statutory courts. As a result, two systems of justice may be said to exist side by side; and it is worthy of note that in some territories the cases decided by the native courts largely exceed in number those decided by the statutory courts. The quality of the justice dispensed by the traditional type of native court is, however, differently assessed by advocates of the direct and indirect systems of rule respectively.

The situation is one which gives rise to a number of difficult questions. Is it possible to evolve from these elements a homogeneous system of law for the whole territory? Is it, again, possible

to modify the procedure of the statutory courts so that they may convey to natives a better impression of their value as sources of justice? Is it possible to provide means by which native customary law can adjust itself to meet the needs of advancing society? Are the methods adopted for the administrative supervision of the native courts, in which admittedly lies the main guarantee for the quality of justice dispensed by them, adequate for the purpose?

The introduction of European law has substituted European types of penalty, and in particular fine and imprisonment, for the sanctions to which native society was accustomed. The African's acceptance of European justice is largely influenced by the views which he holds on the character of those punishments. But though means might with advantage be found for a fuller application of the principle of compensation, it is not easy to find a substitute for fine and imprisonment.

VIII. THE NON-EUROPEAN IMMIGRANT COMMUNITIES

The most conspicuous problem in connexion with these communities arises from the existence of Indians in South Africa and the British East African territories. It must be recognized that, so long as the principle of segregation is accepted in South Africa as regulating relations between the European and other races, Asiatics will share with Africans some of the disabilities which this policy imposes. Apart from disabilities in the matter of political or municipal representation, administrative policy is now felt most strongly by Indians in respect of the law regarding the holding of property in the Transvaal, and the discrimination shown in all four provinces in the application of the regulations regarding licences for trading.

The attitude in regard to Indians is likely to be influenced in the future by the fact that in South Africa increasing numbers of Indians are more interested in the attainment of Union citizenship than in their requirements as a separate community.

In East Africa discrimination is much less marked. The claims put forward by Indians are mainly in regard to the method of political representation, and (in Kenya) the administrative restriction on the holding of land in the Highlands. In these colonies

the future of Indians will be largely conditioned by the advance made by the African population, which has already invaded some of the fields of employment hitherto occupied by Indians.

IX. NATIVE ADMINISTRATION

Systems of native administration have everywhere started with the same history. The difficulty of administering large areas with small staffs obliged governments to make use of the native authorities; it was only at a later stage that they began to consider the type of agency best suited to assist in implementing their policies of material and social development. It was then that differing philosophies of rule led to the conscious adoption of different methods of native administration.

In the Union the future position of the native will be as resident of a state in which the dominant ideals will be those of Europeans; it is possible that the procedure of direct rule, and the policy which prescribes the use of the council as the organ of native local government, are best suited for his peculiar situation. In Southern Rhodesia the regulation of native affairs is still in process of evolution, but policy appears likely to follow that of the Union so far, at all events, as regards the preference for the council system. In Kenya a fully developed system, based on District Councils presided over by an Administrative Officer, with nominated native tribunals, had its origin in a lack of confidence in the capacity of traditional authorities. It is possible that this system is best adapted to the areas in close contact with European settlement, but not necessarily to all parts of Kenya. In French territories the adoption of the principle of direct rule is a natural consequence of the policy which looks to the progressive association of the African with French institutions. But it is now recognized that, where use is made of native authorities as agents of the administration, they should be as far as possible the traditional authorities accepted by the people. In the French view, the great value of their system lies in the fact that it is well fitted to ensure the progressive adjustment of native institutions to changing conditions, and that it makes a strong appeal to the educated class. The Belgian system of native administration, as yet in a state of transition, now assigns to traditional authorities a position which resembles that given to them in

the British system of indirect rule; the scale of powers allowed to them is, however, less than in British territories.

In British colonial areas other than those mentioned the prevailing policy is that of indirect rule. Based on the recognition of traditional sources of authority, such as the chief or group, its most significant innovation lies in the grant to them of financial and executive powers for the purposes of local government. The native authority therefore has full scope for gaining in a defined field, and under official supervision, experience in the exercise of authority, both executive and judicial. The 'native administrations' are perhaps less effective agencies for rapid development than those employed by direct rule; but supporters of the system claim that these disadvantages are outweighed by the greater readiness of the governed to accept innovations which are introduced through the agency of their own authorities. In many areas the system has been far more successful in its working than the procedure of native administration formerly in use; but its real test will come when the traditional native authorities are faced with the necessity of introducing social services on something more than the rudimentary scale to which they are now accustomed. It will be subject to a further test with the growth of political and national aspirations in Africa. The system, as it now operates, results in a series of isolated efforts at local government with no connecting link or means for voicing general opinion, such as the Natives Representative Council of the Union may ultimately provide. Up to the present time the fact that the system makes little provision for recognizing educated opinion has not resulted in open opposition to it; in the future, however, it will inevitably have to meet pressure due to this cause.

The growth of urban communities raises a special problem of local government which extends beyond the necessity for providing housing and social amenities. One of the gravest problems of the future will be the development of a legal and administrative system which will provide for the rapidly growing class whose social life is not assimilated to that of the European, but which cannot be suitably regulated by tribal institutions. It is a problem which so far has engaged more attention in the Union and the Belgian Congo than in the British colonies.

X. SYSTEMS OF DIRECT TAXATION

The need for money for taxation is not the sole cause which produces migration in search of wages and the consequent disturbance of social conditions; the normal economic incentive now operates fully in many parts of Africa. Nevertheless, the present systems of taxation have an effect on the native population which necessitates careful consideration of the form taxation should take. Only in the southern area of the Gold Coast has it been possible to dispense with a direct tax; elsewhere native taxation exists either in the form of the Nigerian system of 'lump-sum assessment' on a village or similar unit, or a poll tax, or a combined hut and poll tax, which in some cases is graduated according to local circumstances, and in others is a rigid flat rate over a whole territory.

Apart from difficulties in collection, which were very marked during the depression period, the growing measure of differentiation in African social economy points to the need for a closer relation between taxation and individual income. It is possible that the Nigerian system, which allows of the consideration of individual circumstances in distributing the lump assessment, may be applicable elsewhere to settled areas which are not dependent on outside wage earning. In areas where wage earning is usual, the introduction of systems of territorial graduation, and means for assuring flexibility in collection, require careful study. The need for more equitable assessment is especially noticeable in non-tribal and urban areas, where a rigid flat rate must produce great anomalies.

XI. THE PROBLEMS OF LABOUR

In the past the demands for tax, and in some areas a degree of compulsion, played a predominant part in the introduction of the African people to European industrial undertakings. As has just been stated, however, the normal economic incentive is now an influence of increasing strength. Compulsion may be said to be confined to narrow limits, being only used by native authorities for communal purposes, or by governments for urgent reasons, or as a partial alternative to the direct tax. Nowhere is acknowledgment given to a system in which labour is compulsorily obtained for private purposes.

The deficiency of labour, which was in earlier days a distinguishing feature of African labour problems, still exists in some areas, but arises more from the fact that the demand of industrial concerns exceeds local supplies of labour than from an unwillingness to enter wage employment. Labour supply is in some areas influenced by the extension of marketable cultivation, and unless a population exists which cannot gain from agriculture the income it needs, employers can only attract labourers by the normal process of improving conditions of employment. In the long run, however, the expansion of marketable production is more likely than is the pursuit of a subsistence economy to produce the additional labour required for industrial development.

Among the general problems which an administration may now have to consider, is the advisability of restricting the employment of labour from certain areas owing to health or social conditions, and the necessity for stimulating the cultivation of subsistence crops where natives have become unduly dependent on wage earning. The Belgian Government may be said to have taken the lead in the study of questions of this type. It is, again, necessary to consider the extension of social services, and some system of provision during unemployment, in the large resident aggregations of natives collected for the purpose of wage-earning and for whose conditions of living industrial concerns have no responsibility. This type of problem exists in especial force in the Union.

The repercussion in other territories, where there are strong European interests, of the Union policy of confining the native to the field of unskilled labour, involves problems which may assume greater proportions as Africans become more alive to their importance in the modern industrial economy. Hitherto capitalist enterprise has been able to count on relatively cheap labour, owing to the fact that wages are for the most part sought for other reasons than that of subsistence. In some areas, the numbers are rapidly increasing of those who are entirely dependent on their wage-earning, and this fact may materially affect the relations of employers and labour. There is as yet little evidence of the growth of a common consciousness among African wage-earners, but the possibility of the combination of African labour in unions or otherwise is one which cannot be ignored.

XII. THE LAND

The policy adopted by governments towards land in Africa was at one period determined by their own conception of the economic use to which land could be put, rather than by considerations regarding the nature of native rights. Their immediate need was the development of resources, which in some areas seemed likely to be achieved by the establishment of a European population, involving the alienation of large areas of land, in others by capitalist undertakings demanding monopolist or similar rights over the produce of the land, and finally in others by the activities of the native population itself, in which case little alienation of land was required. The precise form used by any state in asserting rights for itself, or in recognizing those of natives, was liable to vary according to these circumstances.

The consequences of alienation of land are most conspicuous where native occupation has been confined to reserves demarcated in order to meet the requirements of European colonization. It is, however, unlikely that circumstances will now arise which will make governments again desirous of acquiring land on so large a scale for European settlement. At the present day there are two principal issues regarding land which call for notice. The first relates to the nature of the legal rights which states have established, by legislation or otherwise, over lands which remain in native occupation, and to the precautions which they take to protect the rights of occupiers when acquiring native land for public purposes, or for the establishment of private industrial enterprises. The second problem relates to the type of legal title which the state is prepared to recognize in favour of individuals, over lands now held on customary native tenures.

As to the first point, the present position is, in general terms, that in certain British West African territories and in some smaller areas, such as Buganda, it has been recognized that all lands are native property over which, accordingly, the state can claim no rights. Elsewhere, however, in British as well as French and Belgian territories, the state can in effect expropriate any lands over which it has not given or recognized a title—in other words, the great majority of lands in native occupation; the restrictions

on its action exist only in the form of executive regulations, or, as in the case of reserves in British territories, depend on the assent of the executive bodies who are statutory trustees for these lands. Great importance attaches, therefore, to the character of the regulations or instructions which control the action of the local authority in dealing with native lands.

As regards the second point, the communal system of landholding, using the term 'communal' in the special sense which it possesses in Africa, still prevails in the greater part of the continent. There are, however, areas in which the right of user is becoming more exclusive; in a further relatively small area, a custom has grown up of the allocation of land for individual usage; in some cases leases and sales are recognized. It is clear, however, that usufruct remains the prevailing conception. Over the greater part of Africa it would be premature to take steps to give legal recognition to individual titles; but circumstances (including the need for using land as a basis for credit) will before long make it necessary to undertake this process in some of the more economically advanced areas. There is some difference of opinion, particularly as between French and British authorities, as to the form in which individual title should be recognized; but experience elsewhere as to the necessity for preventing agricultural indebtedness and the fragmentation of land appears to make it advisable that title, at this stage, should be of the nature of 'occupancy' or have a character which, while allowing of the exercise of all the rights of ownership, would limit the power of encumbrance and transfer.

XIII. AGRICULTURE AND ANIMAL HUSBANDRY

At an earlier stage in the history of the agricultural departments attention was largely directed to finding means for increasing the production of export crops. A variety of causes has tended of late years to emphasize the need for the improvement of native subsistence crops. Native agriculture is for the most part based on the system of shifting cultivation. This system is in itself a natural adjustment to the needs of African soils, which require a considerable period for regeneration after cropping, and though it has in the past caused great destruction of high forest, its normal use is not necessarily harmful in other conditions. The settlement of

population in fixed areas, and the pressure on the soil due to the expansion of economic crops, have, however, led to the use of the system in an abnormal manner, with the result that the period of regeneration is unduly curtailed and the vegetal cover destroyed.

As regards animal husbandry, the salient facts are that, over large parts of Africa, tsetse fly makes it impossible to keep domestic cattle; and that in other large areas, particularly in South and East Africa, native custom attaches a semi-religious value to cattle, with the result that overstocking is liable to cause great destruction of pasture and to produce soil erosion.

So far, then, as regards the improvement of native agriculture, the first effort must be to indicate some alternative method for the regeneration of the soil after cropping. Of the different methods examined, one of the most promising appears to be that of mixed farming. Its success, however, will depend on the efforts made to secure protection from infection in tsetse fly areas, and to secure a more economic use of cattle by natives elsewhere. Here, as in many other respects, the departments which deal with agriculture and animal husbandry have a common field of work. The difficulties which lie in the way of the general adoption of mixed farming point to the need for considering other alternatives to the present methods of shifting cultivation, such as green-manuring, composting, or the like. There are, again, problems of a somewhat different class, such as the relief of the more congested areas by redistribution of population, for which provision of water supplies is often required, or the preservation of pastures by introducing a system of rotational grazing. Although native methods of agriculture are rooted in social custom, past experience shows that new methods will be accepted by the people if these can be demonstrated to be adapted to their circumstances.

The question regarding the relative merits of the 'peasant' and 'plantation' system of production is one of the outstanding issues of African economics. It must be realized, however, that there is only a limited field within which the issue has any reality. Certain export crops do not provide an adequate return for capitalist production; there are others in which peasant production can hold its own when quality is safeguarded by official supervision of cultivation or of marketing conditions. There remain a few products for

which 'plantation' methods seem likely to secure a better market. The question whether their production should be encouraged by provision of land or the like is in the last resort mainly one for decision on political as much as on economic considerations.

XIV. FORESTS

In Africa, forests have a function in conserving water supplies and climatic conditions which is often of greater importance than that which they exercise as sources for the supply of timber. The progressive deforestation caused by human action demonstrates the need for expanding the forestry régime in a number of the African territories; but circumstances at the same time require that every effort should be made to secure the co-operation of Africans themselves in the preservation of their woodlands. The creation of a cadre of qualified African assistants, which is in any case necessary for the expansion of forest work, would also contribute to this result. Some governments have sought the co-operation of Africans by establishing 'village forests' and by entrusting the management of reserved areas to 'native administrations'. Some further experience of the operation of the latter measure is, however, required.

In the Union, a policy of afforestation in a territory lacking extensive indigenous timbers has been actively pursued. In British colonial areas the vast extent of thinly populated woodlands presents special difficulties of control, and the forestry staffs, owing to their smallness, have been mainly occupied on problems relating to commercial exploitation. Of French territories, only the Ivory Coast has an effective forestry régime, mostly in connexion with the exploitation of its valuable high forests. In the Congo forestry control has only recently begun. In most territories the immediate need appears to be for a more complete reconnaissance, in order to determine the limits of possible reservation, and also to gain fuller information as to the stocking of the forests with commercial timber.

XV. THE PROBLEMS OF WATER SUPPLY

In very few areas are the conditions of Africa favourable to the construction of large-scale irrigation works, and efforts to improve water supplies must for the most part be confined to inexpensive

methods of rain storage, the provision of drinking water as an aid to the expansion of cultivation, and comparatively small irrigation works. Though South Africa has undertaken some important irrigation works, they have seldom proved remunerative; on the other hand, the importance of water supply to the cattle and sheep industry of the Union has led to the adoption of a policy involving considerable expenditure on the boring of water holes, as well as the subsidizing of dam building by farmers. In most British colonial areas activity centres on the provision of drinking-water supplies, on which the fuller use of native lands largely depends. In French colonies the supply of drinking water forms the main problem, but interest also attaches to the scheme of irrigation in the Niger basin, a work of first-class importance, now approaching completion.

XVI. EROSION

It is not always easy to distinguish erosion due to the action of man from that occasioned by nature; and some discussions on the subject appear to be directed rather towards convicting man of his sins than to ascertaining how much of the mischief done either by nature or by man is capable of remedy. But it is clear that in Africa the process of erosion, caused by shifting cultivation and by overstocking, has been accelerated by modern conditions under which populations are concentrated, more extensive areas of land are cultivated, and the increase of stock is more rapid. The provision of means to counteract the mischief thus done is now one of the most serious problems of Africa, nor can it be said that adequate remedial measures have yet been taken in any territory. It may be added that there appears to be a need for a closer co-ordination of policy between different British territories than exists at present.

XVII. HEALTH

There are no reliable statistics which would enable a comparison to be made between Africa and other territories in respect of the prevalence of disease. The fact remains, however, that malnutrition is a characteristic feature of many parts of Africa; there are low standards of hygiene in many rural areas and in most urban native locations, and there is a marked prevalence of malaria, sleeping sickness, venereal disease, and different forms of

helminthic disorders. Civilization is responsible for part of the mischief it is seeking to remedy; the increasing contact between peoples hitherto living in isolated groups, as well as industrialization, have introduced new problems in the spread of disease.

Policy varies regarding the manner in which the narrow resources available can best be used for the prevention and cure of disease. The French rely largely on a system of medical centres with attached dispensaries and mobile medical units. The Belgians rely on intensive methods of attack on affected areas with the view of clearing them up before handing them over to the care of the normal medical and health services. In the Union and in British territories, policy has favoured the less elastic system of hospitals and outlying dispensaries. In Nigeria the use of a mobile system resembling that of the French territories is now being adopted, in order to deal with an outbreak of sleeping sickness. There seems good reason to hold that the mass infliction of disease of the type existing in Africa demands more direct methods of attack than have hitherto been employed in British territories; that funds should be devoted to organizing intensive medical campaigns rather than to the perfecting of the hospital system, and that, if necessary, statutory powers should be taken to secure that persons suffering from disease should submit to the necessary medical treatment.

The task of the health services in Africa, however, extends beyond the application of modern scientific technique for the prevention and cure of disease; they share in the responsibility of other social services for the improvement of African conditions of life, and their part is the more important because they are concerned with some of the fundamental problems of Africa, such as that of nutrition.

There are in the government service of the British West African colonies over thirty African medical men, with full qualifications gained in Europe. But for the extension of medical work in Africa it is more important to expand the cadre of locally trained medical assistants. France has led the way in the training of this class at Dakar, and in British territories the existing provision will now be increased by the courses instituted at Yaba in Nigeria, Mulago in Uganda, and Fort Hare in the Union.

XVIII. EDUCATION

Only of recent years has systematic thought been given to the form which native education should take in Africa. At an earlier stage opinions as to the instruction to be given were influenced by considerations other than those of educational policy; thus in the Union official opinion would have given to Africans only the instruction suitable for those whose future lay in subordinate positions in European employment, while missionary opinion favoured an education of a European type, as a symbol of native right to equal treatment. In the British colonies, education was left largely in the hands of missionary bodies, and government policy could hardly be said to have declared itself. A change came with the recognition by the government that education must be progressively extended throughout the population. It was recognized that a type of education must be devised suited to the mass of the people; the character of the advanced education to be given to the few must be determined by the choice made, on general grounds, between the alternative policies of keeping higher instruction on a vocational plane, or giving advanced education of a general type to as many Africans as possible.

As a result the educational system in the Union is now coming under revision; current policy appears to indicate the vernacular as the most suitable medium for popular education. In the British colonies the vernacular is now the accepted medium in popular instruction, and an effort is being made to give school courses a content suited to African environment. But native education is still in its initial stages, and the wider employment of Africans in the public services is delayed owing to the lack of candidates fit to receive special training for their work. In only a few areas do more than a small proportion of children of school-going age receive any instruction, and few pass beyond the elementary standards. Primary education is still left to a large extent to missionary bodies; and much of it is necessarily in the hands of inadequately trained teachers.

The most pressing need in regard to popular education in British territories appears to be an effort to make the present policy more effective by providing better means of control and improving

the standards of teaching. As regards advanced education, while present policy recognizes the need for broadening the basis of pre-vocational instruction, the tendency, as shown for example at Makerere and Yaba, is to give preference to advanced instruction of the vocational type. But the future of advanced education must remain in some doubt, until the governments arrive at some definite policy on the position which the native is to occupy in the administrative and technical departments, particularly in areas under a system of indirect rule.

In the French colonies education forms an essential feature in the policy of 'association'. A carefully devised system separates the *élite* from the mass, giving the former a training which engages their sympathy with French culture and makes them efficient 'auxiliaries' in the work of administration. Advanced education is almost entirely confined to supplying the requirements of the government services, a policy which secures that there is no surplus of educated but unemployed Africans. The education given to the mass is as far as possible vocational, and the language of instruction is French. The system is efficient, and any judgment of its value must depend on the view held of the merits of the alternative policies of associating Africans as closely as possible with European civilization, or of assisting them in the evolution of their own characteristic culture.

The chief characteristic of Belgian education is its effort to improve the African's capacity for the work of developing the Congo. Popular education is conducted in the vernacular; there is a strong emphasis on manual training, agricultural instruction, and the like, and higher education is vocational in character.

In the British territories an effort is now being made to test the value of the cinema and broadcasting for influencing large illiterate populations in matters of health and agriculture. Attention is also being directed to the supply of literature, in the form both of vernacular papers and books.

XIX. THE EXTERNAL ASPECT OF ECONOMIC DEVELOPMENT

The continent of Africa as a whole has only a small share in the world's production; it has 4·5 per cent. of the world's export and 4·8 per cent. of the import trade. But Africa has, on the other

hand, a large proportion of the production of certain particular commodities, such as gold, diamonds, chrome ore, palm oil, groundnuts, cocoa, and sisal. Certain of these products have required a large capital outlay to develop, and others have been able to come on the world's market only after government or private enterprise has raised the capital needed for expenditure on communications. The development of Africa has from the first made heavy demands on the supply of outside capital. It is estimated that the total investment in the part of Africa with which we are concerned amounts to £1,222,000,000, of which a large proportion has come from British investors; of this sum, £546,000,000 has taken the form of loans or grants to governments. About 75 per cent. of the total loans raised by governments of British territories was for railway purposes.

Except in the Union it is not easy to foresee a time when foreign obligations will be converted into internal debt, or when the capital necessary for development will be produced locally. Save, however, for possible mineral development, there do not appear to be projects of any magnitude which will in the near future demand an extensive supply of foreign capital. If so, the future addition to Africa's foreign debt is likely to take the form of investments of the 'equity' type rather than of fixed-charge government securities.

The high proportion of fixed-interest obligations of certain of the territories has had a serious effect on their economic position, especially in periods of falling demand. There are now some governments which have to face so heavy a charge on this account as to make it inadvisable for them to attempt to raise fresh loans for development purposes, and if the pace of internal development is to be quickened, it can only be as the result of assistance in the form of free grants from the imperial power which controls them.

XX. THE INTERNAL ASPECT OF ECONOMIC DEVELOPMENT

Africa may be said to have two systems of economy, the European and the native, which meet at the point where the native begins to work for wages in European undertakings, or to take export crops to market. The European type of economy exists in its most complete form in the Union. Here the maintenance of the economic and also the social structure in its present form has been

made possible by the success of the mining industry; what mining has meant to South Africa is best indicated by the fact that up to 1937 the Union had produced minerals (including gold) up to the value of £2,000,000,000. The extent to which agriculture, even now relatively unremunerative and partly dependent on state aid (made possible by taxing the profits of mining), or the secondary industries (which are based largely on the needs of the mining population) would survive a serious decline in mining, is a matter mainly of speculative interest; it is, however, certain that the economic structure would have to undergo a readjustment so far-reaching as to have serious reactions on the social structure. In both the Rhodesias the future of European agriculture is (save possibly for the production of tobacco) also closely linked with that of mining. In East Africa mining is of far less importance in the general economy. It would seem that here European agriculture can only survive competition with native production when it is artificially supported by tariffs or the like, or where special conditions prevail, as for example in the case of sisal, tea, and some types of dairying. The tendency in the future may therefore be for Europeans to move away from general agriculture into commerce or various forms of non-agricultural enterprises.

In the Congo, and in French and British West Africa, farming forms a smaller part of the economy of Europeans, who will doubtless continue to be concerned chiefly with mining or commerce, or the management of plantations. Everywhere, therefore, the progress of the European system of economy is likely in the future to be linked up with the exploitation of mines, with commerce, and with certain specialized forms of agricultural production, generally requiring capital for their development. Save in South Africa and Southern Rhodesia, European enterprise is likely to engage the energies of a special class, non-resident in character, not primarily concerned with retail trade or with occupations involving manual labour.

The native economy includes the large section engaged solely in subsistence production, the growing number concerned also in the cultivation of export crops, and finally that section which combines these forms of production with wage-earning in Euro-

pean undertakings. It is an important fact that a large proportion of such wage-earning is 'part-time' in the sense that family subsistence is drawn from other sources; but in some areas, notably the Union, the situation is undergoing a change involving far-reaching consequences, owing to the growth of a class which is increasingly dependent for subsistence on wage-earning. It will be seen that the native economy, as above described, contains no specialized commercial or trading class; only in West Africa could it be said that such a class exists, but even there the class is not fully specialized. It is mainly in the West, again, that it is possible to recognize an artisan class.

It is not, even at present, possible to look on these two economies as occupying entirely separate fields of activity, and the tendency in the future must inevitably be in the direction of greater fusion. While in the Union or Southern Rhodesia the accepted policy would assign a separate economic existence to the bulk of natives, and confine them to a position subordinate to those who compose the European economy, the possibility of a complete fulfilment of this ideal depends on economic factors (such, for instance, as the continuance of gold production) which may themselves be subject to modification. In many other parts of Africa it is clear, from what has been said, that there is a large field of economic activity into which Europeans are not likely to enter, and even in that on which they have entered there is a wide scope for the native to develop his economic life on lines complementary to those taken by the European. Not only is this so, but the future economic prosperity of some of these countries probably depends more on the general development of native economic activity than on the results of European enterprise. But here, as elsewhere, the factors of economic evolution are not only material but psychological. The African cannot achieve his economic development without a material change in his present social custom, involving, among other things, some measure of individualization in the holding of property and of differentiation in the economic position of individuals and classes, the growth of specialized occupations, including those of the artisan and the trader, and the building up of a social sense which permits of the erection of a credit system and the normal operation of a law of contract.

XXI. CO-OPERATIVE ORGANIZATION

Further experience is required before it is possible to judge clearly of the function which co-operative organizations are likely to perform in native Africa. Save in the Union, in some parts of the West Coast, and in urban areas, there has not as yet arisen a need for the extension of the co-operative movement for the purpose of providing credit facilities. The native societies now in existence, which are principally in Tanganyika, Nigeria, and the Gold Coast, function for the most part in connexion with production and marketing. They owe their success largely to the official guidance given to them, but though they cannot be said to be fully independent, they have their value in stimulating interest in the use of joint action. The French *sociétés de prévoyance* have taken a considerable part in agricultural development; they are, however, official organizations.

It has been suggested that the creation of groups of persons united by interests not shared by the rest of the community is likely to prejudice the position of the institutions on which the system of indirect rule is based. It is very doubtful if this is a necessary consequence; but it would nevertheless be an advantage to associate the native administrations with the working of societies founded within their jurisdiction.

XXII. MINERALS AND MINES

In the Union, the Rhodesias, and the Belgian Congo development has been in the past, and is still to-day, largely dependent on the mining industry; in British West Africa mining has shared its position with the products of native agriculture, while in East Africa it is of relatively recent date. In some other areas, such as French Equatorial and West Africa, it is still of minor importance. But taking Africa as a whole, it may be said that mining has been one of the most important factors responsible for bringing European capital to the continent, and for the introduction of the modern industrial system.

It is not possible to say what capacity exists in Africa for the expansion of mining, more especially of the baser metals, which have hitherto been less exploited than the precious metals. While

the growth of industrialization due to the expansion of mining may doubtless have reactions on African life, demanding the serious attention of the administrations, nevertheless the possibility of developing the finances available for expenditure on the social services in certain of the African territories depends largely on the exploitation of their mineral resources. The share which the governments can take in this process lies mainly in making larger provision for geological survey, and in simplifying the regulations regarding prospecting, mining leases, and taxation. These matters would seem to require a closer attention than has hitherto been given to them.

XXIII. TRANSPORT

Transport has two important aspects: first, the provision of those major lines of communication which make it possible for African products to enter the world's markets, and second, the construction of the road system required for the development of interior trade. In South Africa, the Rhodesias, and the Congo, the mining interests called forth the capital necessary to construct the railways and provide services on the rivers; elsewhere communications were constructed to meet the general requirements of development policy. The cost of these major lines of communication has been estimated at £384,000,000, and though some of the railways have been self-supporting, particularly those serving the richer mining areas, there are many cases where the fixed interest has become a charge on the general revenues of the administration. Where a government has sufficient resources, it is not unreasonable to treat part of the capital cost of a railway as development expenditure, from which no return in interest is to be expected. But few of the African colonies can afford this procedure, and it is not likely that, in the near future, colonial governments will undertake any considerable railway extension, unless experience gained from the use of road transport, or the opening up of large mining undertakings, ensures a prospect of remunerative freight.

The construction of roads serving internal markets has already done much to reduce the amount of head-porterage, which was formerly a cause of much human suffering, and even to-day is the most wasteful form of transport. But there are many areas still in

need of the establishment of internal markets, with the roads necessary to serve them; this is, indeed, an essential step in the evolution of African economy.

XXIV. THE FUTURE OF AFRICAN STUDIES

We see before us now the most formative period of African history, and much that is done to-day will have a decisive effect on the future of the African peoples. The task of guiding the social and material development of Africa gives rise to problems which cannot be solved by the application of routine knowledge; they require a special knowledge, which can only be gained by an intensive study of the unusual conditions. This study must be pursued in the field of the social as well as in that of the physical sciences. But for this purpose assistance is required from the Imperial Government, and it is suggested that this should take the form of a grant to be administered either by a Committee of the Privy Council or by the Economic Advisory Council. For certain types of research the managing body might well make a fuller use of the existing imperial institutions, as an alternative to an extension of the establishments for research maintained in the colonies. It is further suggested that the difficulty which is now felt in readily obtaining information should be met by the establishment of an African Bureau covering social, economic, scientific, and administrative problems, which will constitute both a clearing-house for information and a source of assistance to all those who are pursuing research or inquiry into African questions.

TABLE XVII. *Measures used in the Survey*

1 morgen	= 2·1164 acres.
1 hectare	= 2·4711 acres.
1 kilometre	= 0·62137 mile.
1 metric ton	= 1,000 kilogrammes.
	= 2,204·6223 lb. = 0·9842 English ton.
Long ton	= 2,240 lb.
Short ton	= 2,000 lb.
1 kilogramme	= 2·2046223 lb.
1 square kilometre	= 0·3861 sq. miles.
Bale of cotton	= 400 lb.
Bag of maize	= 200 lb.

ACKNOWLEDGEMENTS

It is impossible to give adequate acknowledgement to all who have helped in various ways in the compilation and scrutiny of *An African Survey*. In the following lists mention is made of those who supplied substantial drafts for chapters or special memoranda, who read the chapters in draft or proof and supplied comments, and who gave assistance in other ways, such as the loan of material, or answers to queries.

J. C. ABRAHAM; Dr. R. F. G. ADAMS; L'AGENCE ÉCONOMIQUE DE L'AFRIQUE ÉQUATORIALE FRANÇAISE; L'AGENCE ÉCONOMIQUE DE L'AFRIQUE OCCIDENTALE FRANÇAISE; Sir Maurice AMOS; G. G. AUCHINLECK.

S. J. K. BAKER; Mr. and Mrs. W. G. BALLINGER; J. Austen BANCROFT; A. M. BECKETT; Monsieur BÉLIME; H. BENNETT (U.S.A.); Monsieur M. BESSON; Miss D. G. BRACKETT; Monsieur M. J. BRÉVIÉ; The BRITISH BROADCASTING CORPORATION; Canon BROMFIELD; Dr. E. H. BROOKES; Major G. St. J. Orde BROWNE; F. BROWNE; C. BULLOCK; Father A. BURBRIDGE.

Sir Donald CAMERON; Professor A. M. CARR-SAUNDERS; A. W. CARRUTHERS; Monsieur A. CHARTON; Dr. C. C. CHESTERMAN; Major A. G. CHURCH; The CHURCH MISSIONARY SOCIETY; The CHURCH OF SCOTLAND FOREIGN MISSION OFFICE; Professor F. CLARKE; Professor H. CLAY; The COLONIAL FOREST RESOURCES DEVELOPMENT DEPARTMENT; J. R. COOPER; Monsieur M. de COPPET; Professor R. COUPLAND; The Rev. H. W. COXILL; The Rev. A. S. CRIPPS; Mr. and Mrs. A. T. CULWICK; The late Sir James CURRIE.

Dr. F. DIXEY; Dr. C. M. DOKE; The Rev. J. W. C. DOUGAL; C. E. DUFF; H. J. E. DUMBRELL.

Major P. Granville EDGE; F. J. ERROLL; Dr. Ifor L. EVANS; The Rev. D. V. EVENING.

S. H. FAZAN; A. J. FINDLAY; G. H. FINDLAY; Dr. R. W. FIRTH; Dr. D. C. FISHER; Professor C. Daryll FORDE; Dr. M. FORTES; Professor S. H. FRANKEL; Major R. D. FURSE.

The Index has been compiled by Miss S. F. STALLMAN, M.A., and Dr. M. LAMBERT, B.A., PH.D.

INDEX

NOTE: As far as possible the Index has been arranged so that details of subjects appear under territorial headings. Provinces of territories are placed at the end of each territorial heading. To facilitate reference the more important entries have been repeated at head of columns.

Abercrombie, Dr. J., Edinburgh Medical Mission founded by, 1116.
 Aberdeen Research Station, *see under* Northern Rhodesia.
 Aborigines Rights Protection Society, Gold Coast forest legislation opposed, 1002.
 Abyssinia: diseases, leprosy, prevalence, 1140; refugees in Kenya, financial assistance, 1446.
 Abyssinian Plateau, elevation and relief of, 3.
 Achimota College, *see under* Gold Coast, education (native).
 Achour, tax in Fr. W. Africa, 589.
 Acoli language, 77, 88.
 Adams, R. F. G., Ibo grammar, 92.
 Administration: inter-departmental co-operation, 1612; systems in African dependencies, summary, 1641.
 Afoa, *see under* Belgian Congo, industrial concerns.
 AFRICA: eastern highland area, 3; government—considerations affecting form of, 246-7;—problems of, 254-5;—systems, general conclusions, 246-60, 1641; languages, *see under* Language; physical features of, 1-4;—summary of, 1666; peoples of, *see under* Peoples; population—capacity, 124-5;—statistics, 108, 109 (*see also under* Population); Rift valley system, 3; special problems, 1611-12.
 'Africa' Orthography and Alphabet, *see under* Language.
 Africa, periodical publication, 1633.
 African Bureau: financial aspects, 1635; organization and functions, 1634-5; recommended, 1662.
 African culture, importance of anthropological study, 1637.
 African Explosives and Industries Company, agricultural research by, 946.
 African Lakes Corporation: Nyasaland concession acquired, 705; anti-slavery campaign assisted, 1538; operation in Nyasaland, 1385.

African Life and Languages, School of, *see under* Universities, University of Capetown.

AFRICANS, EMPLOYMENT: agricultural demonstrators, 965-8; Agricultural Department officials, 964; civil servants, 233, 234, 235-7, 239, 241, 255-60, 1642-3; dentists, 1169; doctors—'auxiliary', 1172-3, 1177;—limitations on private practice, 1183; engine drivers, 692, 1581, 1586; forest guards, 995, 996, 1003, 1004, 1007; forest rangers, 996, 1000, 1002, 1004; foresters, 995, 998, 1002-4, 1020-1;—recommended, 1652; health services subordinate staff, 1115, 1156-7, 1159, 1162-3, 1166-8, 1170-4, 1176-7, 1179, 1181; industrial work, capabilities, 1427-8; medical assistants, 1168-9, 1275;—conclusions, 1654; medical officers, 1168, 1169-70; microscopists, 1162; postal servants, 692; skilled labour, training in Belgian Congo, 1274; survey work, 9, 10; telegraphic services, 692; training in agriculture, *see under* Agriculture, native education; Education, native; tsetse reduction measures, 1132; wireless staff, 1299.

Afrikaans language, use of in education, Union of S. Africa, 1212.

Agni people, land tenure customs described, 840.

Agriculture.

Advisory Committee on Agriculture and Animal Health, 1627; capitalist enterprise, uses and benefits, 983; concessions system, 981; conferences, *see under* Agriculture, research.

CROPS:

bananas: cultivation requirements, 901; European production, 919;—Br. Cameroons, 928;—Fr. Cameroons, 928;—Fr. W. Africa, 928; export trade, 901-2; liquor brewed from, 901; native cultivation, 901-2; origin of, 883.

Agriculture—Crops (*cont.*)

- beans: European cultivation, 919;
native food, 888.
- beeswax, native production, 891.
- cacao (*Theobroma cacao*) and cocoa:
cultivation requirements, 906-7;
deforestation prejudicial to, 1103;
European cultivation, 919; export
destination, 1332; introduction to
Africa, 907; native cultivation, 907-
9; Nigeria, 951; origin, 883-4; pro-
duction, 1326;—British dependen-
cies, 1332; varieties grown, 908.
- cash, ecological survey, N. Rhodesia,
954; erosion increased by, 1078;
taxation, 596.
- cashew nuts, native production, 917.
- cassava (manioc): cultivation, 896;
disease, 896; native cultivation,
895-6; native food, 888; origin, 883;
toxic qualities, 896; varieties, 896.
- cinchona, European production, 920.
- cloves, origin, 884.
- coco-nuts and copra: native produc-
tion, 914; origin, 884; palm cultiva-
tion for, 914.
- coco-yams (*Colocasia antiquorum*): culti-
vation requirements, 897; native cul-
tivation, 897; toxic attributes, 897.
- coffee: cultivation requirements, 909;
European cultivation, 919, 920, 923-
4; native attitude to, 909; native
cultivation, 909-11, 923-4; origin,
884; pests, control work, 910, 970;
production, 1326; Tanganyika ex-
ports to Kenya, 1330; varieties
grown, 909.
- cotton: Cotton Research and Indus-
trial Board, work, 903; commercial
varieties grown, 903; cotton-seed
oil, experiments for utilization, 905;
cultivation requirements, 902; Em-
pire Cotton Growing Corporation,
research stations, 1622; erosion and
cultivation, 1099; European pro-
duction, 922-3; exports, destination,
1332; Gezira scheme and cultivation
of, 1054-5; ginned production, 1327;
indigenous and imported varieties,
902; native production, 902-6, 922-
3; origin, 884; pests and control,
903, 970; seed production, 1327;
varieties grown, 905, 906.
- cover, *Mucuna*, 962.
- cucumbers, native food, 888.

Agriculture—Crops (*cont.*)

Station, 957.
- diseases, 970-1; *see also under* Agricul-
ture, research.
- eleusine, native cultivation, 893-4.
- essential oils: European cultivation,
919; grants from Colonial Develop-
ment Fund, 919.
- fruit: citrus, 917-18; European pro-
duction, 918, 920, 927-8;—in Belgian
Congo, 928;—Union of S. Africa,
918; native cultivation, 891.
- gero, *see under* Agriculture, crops
(pennisetum).
- ginger, native cultivation, 890.
- groundnuts, cultivation and uses, 897;
European cultivation, 919; exports,
origins, 1332; native cultivation,
897-9; native food, 888; origin, 883;
production, 1326.
- Guinea corn, *see under* Agriculture,
crops (sorghum).
- jute, native production, 890.
- kaffir corn, *see under* Agriculture, crops
(sorghum).
- kola nuts, 1014; European production,
919; native, 890.
- maize: cultural methods, S. Rhodesia,
921; European production—N. Rho-
desia, 921;—S. Rhodesia, 919, 920;
—Tanganyika, 921;—Union of S.
Africa, 918, 920; native cultivation,
891-3; native food, 888; origin, 883;
soil requirements, 891.
- melons, native cultivation, 891.
- millet, bulrush, *see under* Agriculture,
crops (pennisetum).
- millet, finger, *see under* Agriculture,
crops (eleusine).
- millet, great, *see under* Agriculture,
crops (sorghum).
- millet, lesser, *see under* Agriculture,
crops (pennisetum).
- millet, native food, 888.
- Mundulea, research on cultivation,
Amani Station, 957.
- oil-seeds, 1014.
- oil palms, European cultivation, 919.
- palm products: improvement schemes,
912; industry, development, 911;
native production, 911-14; palm ker-
nels—exports destination, 1332;—uses,
911; palm oil—exports, origin, 1332;
—extraction, 911;—production, 1326.

Agriculture—Crops (*cont.*)

- paw-paw, native cultivation, 891.
- peas, native food, 888.
- pennisetum: awned type, Kenya, 949; cultivation, 894; native cultivation, 893-4.
- pennisetum (bulrush millet), origin, 883.
- pepper, native food relish, 888.
- pests, *see under* Agriculture, pests.
- piassava: cultivation, 890; exports, 889-90; native cultivation, 889-90.
- plantains: cultivation requirements, 901; liquor brewed from, 901; native cultivation, 901-2; native food, 888.
- potatoes: cultivation, 889; European cultivation, 919.
- potatoes, sweet: nutritive value, 889; origin, 883; propagation and cultivation, 889.
- pulses: native cultivation, 900-1; phaseolus bean in W. Africa, 900; varieties, 900.
- pumpkins, native food, 888.
- pyrethrum: European cultivation, 919; exports from Kenya, 919; investigation grants from Colonial Development Fund, 919; malaria control, 1126.
- research, *see under* Agriculture, research.
- rice: European cultivation, 919; indigenous species, 894; native cultivation, 889, 894-5; origin, 883; terracing for, 1064.
- rotation: experimental work, 962; scientific application advocated, 960.
- rubber: 1014, 1016; Congo Free State monopoly, 791; European production, 919; native cultivation, 890; Nigerian lease, 770; production, 1326-7; wild rubber, 890.
- sesame (*simsim*): cultivation requirements and methods, 899; native cultivation, 899-900; production of, 1326.
- shea nuts: 1014; native production, 890.
- simsim*, *see under* Agriculture, crops (*sesame*).
- sisal: European production, 919, 926; exports, destination, 1332; Indian production, 926; production, 1326; —in British dependencies, 926, 1332.

Agriculture—Crops (*cont.*)

- sorghum, native cultivation, 893-4; origin, 883; soil deterioration through, 1088; value of plant, 894.
- soya bean, experimental cultivation, 901.
- spinach (wild), native food, 888.
- sugar: European production, 918, 919, 928-9; Indian production, Kenya, 929; origin, 883; sugar cane, native food, 888.
- tea: European production, 919, 920, 924; international restriction scheme, 1386.
- tobacco: cultivation requirements, 915; European cultivation, 915-16, 918, 919, 925-6; native coarse, 915; native cultivation, 915-17; in Nyasaland, 925; pests and disease control, 970; production, 1326; varieties grown, 917.
- tomatoes, native food, 888.
- wattle: cultivation for erosion-control, 1097; native cultivation, 890; tan stuffs produced from, 1014.
- wheat: European production, 918-19, 921-2; native cultivation, 889; origin, 883.
- yams (*Dioscorea*): cultivation requirements, 897; native cultivation, 896-7; native food, 888.
- Cultivation, erosion caused by, 1057, 1061.
- CULTIVATION METHODS: composting, erosion reduced, 1066; cover crops, erosion control, 1065; manures, green, erosion reduced, 1065-6; mixed farming, erosion reduced, 1065-6; plough, influence on erosion, 1078, 1085, 1100; rotation of crops, erosion control, 1065-6; strip cropping, erosion control, 1065; terracing, value, 1064-5.
- Dairying, *see under* Agriculture, livestock.
- EUROPEAN: Belgian Congo, 919-20; co-operation, Union of S. Africa, 1468; co-operative organization, 1467-71; Fr. Cameroons, 919; Fr. Equatorial Africa, 919; Fr. W. Africa, 919; future of, conclusions, 1658; Gold Coast, 919; Kenya, 919; main characteristics, 918; maintenance, question reviewed, 1394-6; Nigeria, 919; N. Rhodesia, 919; Nyasaland, 919; prospects and future, 1394-6;

Agriculture—European (*cont.*)

Sierra Leone, 919; S.W. Africa, 918; S. Rhodesia, 918; suitability to Africa, question examined, 1395-6; Swaziland, 918; Tanganyika, 919; Uganda, 919; Union of S. Africa, 918.

LABOUR: migration, 699; native conditions in Union, 673; squatter, 724-5; supply, 695-6; *see also under* Labour.

LIVESTOCK:

areas unsuitable through tsetse infestation, 1129.

breeding: Belgian Congo, 953; castration question, 975-6; clarification of policy needed, 976; difficulties in tropical areas, 976; experimental work for improvement, 974-7; Fr. Cameroons, 953; imported cattle a question of suitability, 975; native attitude, 882-3; Nigeria, 950; Portuguese colonies, 953; research—N. Rhodesia, 1466;—S. Rhodesia, 947; Uganda, 950.

cattle: Africa, suitable for, 930; Afrikaner—breeding work, 975;—description, 931; breeding importation, disease susceptibility, 932; breeds imported for crossing, 931; death of, failure to report—in Kenya, 660;—in Tanganyika, 660; Hamitic Longhorn, origin, 930; Malinke, disease resistant character, 976; meat industry, 937-9; native stock rearing, methods, 932; N'Dama—disease-resistant character, 977;—origin and distribution, 930; origin of African, 883; overstocking in Kenya reserves, 811-13; pastoral tribes, distribution, 929; quarantine regulations—effect on industry, 936-7;—and overstocking, 937; shorthorn (*Brachyeros*), origin, 930; slaughter, native attitude, 937-8; slaughter cattle, 937-9; social aspect of and influence on labour, 694; squatter-owned in Kenya, 755; tsetse fly and distribution of, 929; W. African shorthorn—evolution, 930-1;—trypanosomiasis resistant, 929; zebu—description, 931;—disease resistant, 931.

chicken: native industry, 929-30; place in native life, 929-30.

culling: measures for, 973; native attitude, 882.

Agriculture—Livestock (*cont.*)

dairying, 941-3; ghee, native production, 941-3.

dipping: as disease preventive, 974; provision for, 974.

disease: anthrax—area of infection, 935-6;—and control measures, 936; contagious pleuro-pneumonia—area of infection, 935;—control measures, 935;—and vaccination, 935; control and erosion danger, 1079; East Coast fever—area of infection, 934;—preventive measures, 935;—and research, Union of S. Africa, 946;—Uganda, 949; foot and mouth—area of, 935;—research, S. Rhodesia, 947; imported cattle susceptible, 933; prevalence, 932; rinderpest, 931;—control, 1079;—epidemic (1896), 933-4;—its effect on S. Rhodesia, 1379;—and immunization, 934;—vaccination, experiments, Fr. Cameroons, 934;—vaccination methods and efficacy, 934; trypanosomiasis, 931;—area of infestation, 932-3;—preventive measures, 933;—treatment, 933; tuberculosis, 1140;—area affected, 936.

fencing: as disease preventive, 974; and paddocking, 971-2; progress made, 974.

fodder crops cultivation, 972-3.

goats: Angora introduced, 932; decrease advocated, 1111-12; destructive feeding, 1097; disease resistance of, 932; overstocking, 1095-6; place in native life, 929.

grazing, rotational, as conservation method, 971-2.

hides and skins, production and trade, 939-41.

irrigation for stock raising in Union, 1032-3.

management: destocking as anti-erosion measure, 1068-71; grazing areas—burning, value, 1068;—controlled burning as anti-erosion measure, 1067-8;—drought resistant plants as anti-erosion method, 1068;—improvement of grasses as anti-erosion measure, 1068;—kraaling and erosion, 1067;—overgrazing and erosion, 1060;—rotational grazing as erosion control, 1066-7; training provision in, 977-8.

Agriculture—Livestock (*cont.*)

- native attitude towards, 882-3.
- neglect, punishable in N. Rhodesia, 660.
- nutrition, pasture deficiencies, 972.
- overstocking: causes, 971; control needed, 1109, 1111-12; Gold Coast, 1103; by natives, 882; effect on productivity of land, 1063; question of, 1079-80, 1084, 1085, 1086, 1094, 1095-6, 1097, 1099, 1100-1; well sinking as relief, disadvantages, 1062.
- pigs, 939.
- sheep: breeds imported for crossing, 931-2; native, 929; native types, 931; wool, production, 941, 1326.
- tax: advantages and disadvantages, 597; assessment Fr. W. Africa, 590; in Fr. Cameroons, 592; in French dependencies, 589; in Nigeria, 589; *jangali*—in Br. Cameroons, 583;—in Nigeria, 577-8.

MANURE:

- compost: anti-erosion use, 1094; manufacture and experiments, 963; Nairobi factory, 963.
- composting: methods suggested, 962-3; suitability to native methods, 960.
- green: erosion control uses, 1094; extended use, 960; *Mucuna*, its uses and disadvantages, 962; research on—in Nigeria, 950;—in S. Rhodesia, 921.
- mulching, coffee cultivation, 910.
- systems required, 880.
- Marketable crops, *see under* Agriculture, crops (cash).

NATIVE:

- agricultural shows and improvement in, 968.
- Bantu practices, 22-3.
- capital and credit, problem of supply, 1428-9.
- capitalist enterprise and effect on, 983.
- character of, 880-1.
- chief industry, 979.
- chitemene*: harmful effects, 1088; Rhodesian form of shifting cultivation, 879; system, 1088.
- collective farming and improvement of, 966.
- communal labour for chiefs, 881.
- competitions and improvement in, 968.
- COMPULSORY PRODUCTION: Belgian dependencies, 633-4; British depen-

Agriculture—Native (*cont.*)

- dencies, 631-2; comparison with Dutch East Indian system, 715-16; French dependencies, 632-3; marketing, 634-5; Portuguese colonies, 635; system discussed, 634-5.
- conservatism in methods, discussed, 886-7.
- co-operation: considerations governing, 1405; scope for, 1404; uses, 982-3.
- co-operative societies, possibilities, 1466.
- credit: present system, 1429; restricted by transfer difficulties, 854.
- CROPS: 888-917; cash, 888;—effect on subsistence crops, 961; maize, 892; finger millet, proposed reduction in Nyasaland, 1090; palm groves, native tenure rights studied in Belgian Congo, 841; subsidiary, 888; subsistence, 888-91;—improvement needed, 961; varieties grown, 883-4.
- EDUCATION: anti-erosion, Tanganyika, 1092; demonstrators trained—Fr. W. Africa, 1269;—Union of S. Africa, 1222; Fort Hare, Union of S. Africa, 1818; Fr. W. Africa, 1266; livestock management, as anti-erosion measure, 1669-70; need for facilities, 961; training facilities, 964-8.
- 'educative' cultivation: 629; in Belgian Congo, 893, 906, 911.
- European occupation and effect on, 884-5.
- European science and development of, 887.
- food production, decrease, 886, 978-9.
- garden cultivation, crops grown, 888.
- garden system, changes in, 884.
- implements: 881; plough, doubtful benefit, 885.
- IMPROVEMENT: 1395; *Cadulac* organization, 953; capital and credit facilities, problem of supply, 1428-9; for economic development, 1416-17; government collaboration, 1405; and land tenure rights, 837-8; need, 1404; summary and conclusions, 1650-1.
- indebtedness, 872-3.
- labour demand, its influence on, 885, 979-80.
- labour migration and effect on, 704.
- land restriction and effect on, 885.

Agriculture—Native (*cont.*)

land tenure systems, impediment to credit facilities, 1429–31.

LIVESTOCK: dairying, ghee dairies, 1421; European occupation and increase in, 886; goats for bride-price payment, 1079; hides and skins, curing depots, 1421; increase, reasons, 1079; increased sales as anti-erosion measure, 1069–70; manure, native neglect, 883; overstocking, 886; products, attempts to increase consumption, 1069–70; social and religious conception, 882–3; uneconomic, attempts to curtail, 1069–70; veld burning causes erosion, 1067. marketing: inquiry into needed, 1614; produce regulation and grading, 1421–2.

mtayage system, 884.

mixed farming: description of system, 963; development in Nigeria, 963; development recommended, 961; experiments, Belgian Congo, 953; extension possibilities, 963–4; manure utilization in Nigeria, 883.

'mounding': anti-erosion effect of, 1103; system, 880.

non-native enterprise, its value for, 983.

overstocking problem, and Bantu, 22.

peasant production, 884; British policy, 981–2; crops suitable, 980–1; merits and disadvantages, 980–3.

plantation system, development in Gold Coast, 884.

population dependent on, 1416.

production: basis for calculation, 959; compulsory stimulation, 630–5; for sale and export, effect on, 884.

publications, journal in Transkei, 966.

rotational bush fallow system, 880.

SHIFTING CULTIVATION, 879–80; *chitemene* system, 879–80, 1088; deforestation, 985; demarcation of forest reserves, 1021–2; improvements suggested, 960; increase and erosion, 1077–9; land restriction and, 885; practised by Bantu, 22–3; savannah forest as basis for, 986; security of tenure under, 867–70; soil deterioration under, 885; village conditions and, 881–2.

small holdings: in Tanganyika, 969; in Uganda, 969.

Agriculture—Native (*cont.*)

social economy of, 880–1.

soil productivity affected by, 880.

study of systems necessary, 960.

subsistence crop economy, 879.

systems of: and land tenure, 869–70; reorganization for erosion control, 1109.

taxation and influence on, 884–5.

traditional methods, rotational grazing, 1067.

women: food production, 888–9; place in, 881.

Non-native: erosion, tobacco farms, Nyasaland, 1089.

Pasture lands: burning system, 1080; scientific management needed, 1109.

Peasant and plantation production compared, 1403–4, 1651–2.

PESTS:

banana, research in Uganda, 950.

cacao research: Gold Coast, 951; Nigeria, 950.

cassava research: Amani Station, 956; Nigeria, 950.

citrus research, Gold Coast, 951.

coco-nut palm, 914.

coffee: control in Uganda, 910; in Kenya, 923; research—Amani Station, 956;—Kenya, 949;—Tanganyika, 948.

cotton: control in Nyasaland, 903; research—Nigeria, 950;—S. Rhodesia, 922;—Uganda, 949.

crops, control measures, 970–1.

locusts, *see under* Locusts.

striga control in S. Rhodesia, 921.

ticks, destroyed by veld burning, 1068.

tobacco research, Nigeria, 950.

weeds, noxious, eradication efforts, 970.

wheat, in Kenya, 918, 921–2.

yam research, Nigeria, 950.

Plantation system: 980–3; crops developed under, 981; versus peasant cultivation, summary and conclusions, 1651–2.

Populations dependent on, comparative figures, 1416.

PUBLICATIONS: Belgian Congo, 958; B. E. Africa, 958; East African Agricultural Research Station, Amani, 958; French dependencies, 958; Ruanda-Urundi, Belgian mandated territory, 958; Union of S. Africa, 958.
